# ANALYSIS FRAMEWORK for the Trans Canada Highway Corridor Management Plan (Kamloops to Alberta Border) 

Prepared for:
Ministry of Transportation and Highways, Planning Department, Thompson/Okanagan Region Kamloops, B.C.

## Prepared by:

ADI Limited
Victoria, B.C.

## Table Of Contents

1. INTRODUCTION ..... 1
2. SEGMENT AND CORRIDOR DELINEATION ..... 3
2.1 Segment Delineation ..... 3
2.2 Highway Corridors ..... 4
3.0 PERFORMANCE MEASUREMENT AND PROBLEM DEFINITION ..... 7
73.1 Provincial Objectives ..... 7
3.2 Objectives for the Provincial Highway Plan ..... 8
3.3 General Approach ..... 8
3.4 Travel Speed ..... 9
3.4.1 Corridor Speeds ..... 9
3.4.2 Segment Travel Speeds ..... 11
3.5 SAFETY ..... 15
3.6 Reliability ..... 18
3.7 Pavement Condition ..... 19
3.8 Bridge and Major Structure Rehabilitation ..... 22
3.9 Seismic Needs ..... 25
4.0 FORECASTS ..... 26
4.1 INTRODUCTION ..... 26
4.2 Select a Permanent Count Station ..... 26
4.3 Characterise Traffic Generation ..... 27
4.4 Historical Population and Traffic Statistics. ..... 29
4.5 Correlate Historical Traffic and Population. ..... 29
4.6 Forecast Future Traffic ..... 30
4.7 Translate to the Local area ..... 31
4.8 Design Hour Volume ..... 33
3. BENEFIT COST ANALYSIS ..... 35
5.1 Introduction ..... 35
5.2 Economic Data ..... 36
5.3 Project Data ..... 36
5.4 Vehicle Operating Costs ..... 36
5.5 TRAFFIC ..... 38
5.5.1 Vehicle Classification ..... 38
5.5.2 Traffic Growth ..... 39
5.5.3 Traffic Profiles ..... 39
5.5.4 Speed/Flow Relationships ..... 41
5.5.5 Passing Lanes or Short 4 Lane Sections. ..... 41
5.5.6 Access. ..... 42
5.5.7 Summary of Traffic Inputs. ..... 43
5.5.8 Value of Time ..... 43
5.6 Accident Costs ..... 44
5.6.1 Unit Costs. ..... 44
5.6.2 Base Case Accident Rates. ..... 45
5.6.3 Base Case Accident Severity ..... 45
5.6.4 Proposed Case Accident Rate ..... 48
5.6.5 Proposed Case Accident Severity ..... 48
5.6.6 Intersections ..... 48
5.6.7 Reporting the Benefit Cost Results ..... 49
6.0 MULTIPLE ACCOUNT EVALUATION ..... 50
6.1 Introduction ..... 50
6.2 SYSTEM LEVEL OPTIONS ..... 50
6.3 MAE Accounts ..... 50
6.4 Financial Account ..... 52
6.5 Customer Service Account ..... 52

# Analysis Framework <br> Trans Canada Highway <br> Corridor Management Plan <br> Kamloops to Alberta Border 

## 1. Introduction

This analysis framework has been developed as a tool for the Trans Canada Highway (TCH) Kamloops to Alberta Border corridor management plan (CMP). It is not intended to be definitive, but to assist the Ministry in the development of its planning process and products. While designed for the TCH, the framework includes components which could also be applied to any other CMP, Systems Plan or the Provincial Highway Plan :

- Corridor Segmentation
- Performance Measurement
- Benefit Cost Analysis
- Multiple Accounts Evaluation
- Population Forecasts
- Accident Reduction Factors

This analysis framework has been developed to support CMPs in guiding operational, maintenance, rehabilitation, capital and management or policy decisions affecting a corridor. The CMP does this using tools such as performance measurement, Multiple Account Evaluation, and benefit/cost analyses to examine the technical, financial, economic, social and environmental issues surrounding development of the corridor.

Improvements recommended through this framework must consider the potential upstream and downstream impacts on the overall performance of the associated corridor(s). This encourages the practitioner to look at a corridor investment package in the context of a provincial transportation role rather than a series of stand alone projects. Under this framework, the analyses do more than assess highway plant deficiencies. They also take direction from the Provincial Highway Plan's (PHP) goals and objectives which represent Provincial and Ministry goals, growth strategy initiatives, other modal plans, and public input.

Through this process corridor improvements and regional system plan improvements are integrated into a Provincial strategy to help the Ministry:

- facilitate decision making,
- develop business plans to achieve its corporate strategies,
- acquire funding and FTEs, and
- implement investment plans.

Therefore every CMP needs to culminate in a recommended investment strategy with three time frames:

- a short term investment plan (1 to 5 years);
- a medium term investment plan ( 6 to 15 years), and
- a long range investment plan (16 to 25 years).

The short term investment plan represents current corridor needs which are ordinarily more tangible than medium and long range plan future needs, which are less tangible being based upon forecasts over a 25 year planning horizon and which may be subject to changing provincial and local priorities.

## 2. Segment and Corridor Delineation

### 2.1 Segment Delineation

Segments should represent a logical breakdown of a highway into reasonably homogeneous highway sections which could be used for corridor analysis. As such, segments should be delineated so they may be rolled up into sub-corridors and corridors. Generally they are delineated by:

1. Service Class
2. Urban (population $>5,000$ ) or Rural land use
3. Major changes in terrain
4. Major highway junctions

These are a minimum. Finer segmentation based on additional criteria such as accident rate, access density, pavement condition, traffic volume, highway closures, travel speed etc. could also be considered in delineating smaller segments. They can always be applied at the corridor planning stage, but are not used here for several reasons:
a) Most other factors are correlated to the 4 items above (i.e. speed and access are usually correlated to land use and service class)
b) The number of segments becomes unmanageable at the Provincial Highway System level
c) Highway characteristics are saved as continuous data not forced into discrete segments.

Discrete segments are not needed for data storage purposes. In digital files, it is more effective to store data in the segment length appropriate to the parameter being measured. There is no reason for example to force a segment of deteriorated pavement to fit into a segment of highway delineated according to land use. This results in the pavement data being "buried". What is needed is the location where the deteriorated pavement starts and ends. Segments defined later will then show how much of the segment has deteriorated pavement instead of a value averaged over the segment length.

The Ministry's LKI (Landmark Kilometer Inventory) system dated 1 April, 1995, is used to delineate segment break points. Segments proposed for the TCH - Kamloops to Alberta Border, are presented in exhibit 2.1.

Exhibit 2.1
Proposed Segments Kamloops to Alberta Border

| Start Segment | $\begin{aligned} & \text { Start } \\ & \text { km } \end{aligned}$ | Start Description | Length (km) | Basic <br> Lanes | Service Class | Land Use | Terrain |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2050 | 0 | Afton Interchange | 12.07 | 4 | UF | Uban | L |
| 925 | 0 | Yellowhead F/O \#2379 | 4.97 | 4 | UA | Urban | L |
| 925 | 4.97 | Tanger Rd (E. of Kamloops) | 20.93 | 4 | UE | Urban | L |
| 935 | 0 | Hwy 97 at Monte Creek | 27.42 | 2 | RA | Rural | L |
| 935 | 27.42 | Chase West Exit | 11.18 | 2 | RA | Rural | M |
| 935 | 38.6 | Squilax Bridge \# 0481 | 6.95 | 2 | RA | Rural | L |
| 935 | 45.55 | Cobeaux Road \#102 | 3.46 | 2 | UA | Urban | L |

|  |  |  | 441.46 |  |  |  |  |

### 2.2 Highway Corridors

Highway corridors are defined as a "strip of land between two termini, over which traffic, topography environment and other characteristics are evaluated for transportation purposes". How a corridor is delineated depends on what is being analyzed. "Corridor" plans usually address relatively small sections of highway in a great amount of detail. Provincial Highway planning is concerned with corridor performance at a higher level and uses a length equivalent to a long distance trip taking several hours or more to make.

For this analysis, highway corridors are defined at two levels including major corridors and sub-corridors.

## Major Corridors

These are intended to show overall performance of a highway corridor without regard to the performance of individual segments. The performance is measured over a length of highway used which might be used for long distance trips of a day or more. Nine major highway corridors in the Province are identified:

| Highway 3 | Hope to Alberta Border |
| :--- | :--- |
| Highway 16 | Prince Rupert to Tete Jaune Cache |
| Highway 5/16 | Kamloops to Alberta Border |
| Highway 1/5/1 | Vancouver to Alberta |
| Highway 97 | U.S. Border to Yukon |
| Highway 1/97 | Hope to Yukon |
| Highway 1/19 | Victoria to Port Hardy |
| Highway 99 | Vancouver to Clinton (Hwy 97) |
| Highway 37 | Terrace to Yukon |

## Sub-Corridor

In some cases, such as highway closures or corridor studies for example, it is useful to consider something shorter than one of the nine major corridors. The sub-corridors are delineated in exhibit 2.2 by major population centers or highway junctions.

Exhibit 2.2

## Sub-Corridors

| Sub Corridor Number | Hwy | Start <br> Description | End <br> Description | Distance |
| :---: | :---: | :---: | :---: | :---: |
| 1 |  | Highway 1/5/1 - Vancouver to Alberta Border Corridor |  | 818.68 |
|  | 1 | Ferry Toil Booth (Horseshoe Bay) | Clover Valley Underpass (Hwy 15) | 53.43 |
| 2 | 1/3 | Clover Valley Underpass (Hwy 15) | Othello Interchange (Hwy 5/3) | 121.99 |
| 3 | 5 | Othello Interchange (Hwy 5/3) | Afton Overpass (Hwy 5/1) | 196.07 |
| 4 | 1 | Afton Overpass (Hwy 5/1) | Intersection Hwy 97A (Sicamous) | 150.88 |
| 5 | 1 | Intersection Hwy 97A (Sicamous) | Alberta Border | 290.58 |
|  |  | Highway 1/97 - Hope to Yukon Border Corridor |  | 1878.74 |
| 6789 | 1 | Intersection Hwy 1/3 (Hope) | Intersection Hwy 1/97 (Cache Creek) | 193.46 |
|  | 97 | Intersection Hwy 1/97 (Cache Creek) | Intersection Hwy 97/16 (Prince George) | 431.42 |
|  | 97 | Intersection Hwy 97/16 (Prince George) | Intersection Hwy 97/2 (Dawson Creek) | 405.96 |
|  | 97 | Intersection Hwy 97/2 (Dawson Creek) | Yukon border | 947.9 |
| 10 |  | Highway 3 - Hope to Alberta Corridor |  | 830.04 |
|  | 3 | Orthello Interchange (Hwy 5/3) | Alberta Border | 830.04 |
|  |  | Highway 16 - Prince Rupert to Tete Jaune Corridor |  | 1088.28 |
| 11 |  | Rail Crossing © Fairview Terminal (Prince Intersection Hwy 16/97 (Prince George) Rupert) |  | 797.45 |
| 12 | 16 | Intersection Hwy 16/97 (Prince George) | Intersection Hwy 16/5 (Tete Jaune) | 260.84 |
|  |  | Highway $6 / 16$ - Kamloops to Alberta Corridor |  | 415.02 |
| 13 | 5/16 | Intersection Hwy 5N/1 | Alberta Border | 415.02 |
|  |  | Highway 97 - US to Trans Canada Highway Corridor |  | 253.93 |
| 14 | 97 | Canada/US Border | Intersection Hwy 97/3A (Kaleden) | 51.5 |
| 15 | 97 | Intersection Hwy 97/3A (Kaleden) | Intersection Hwy 97/97A (Swan Lake) | 136.98 |
| 16 | 97A | intersection Hwy 97/97A (Swan Lake) | Intersection Hwy 97A11 (Sicamous) | 65.45 |
| 17 | 978 | Intersection Hwy 97A97B (Grindrod) | Intersection Hwy 97B/1 (East of Salmon Arm) | 14.39 |
|  |  | Highway 1/19 - Victoria to Port HardyCorridor |  | 500.86 |
| 18 | 1 | Tolmie Avenue (Victoria) | George Pearson Bridge (Nanaimo) | 109.45 |
| 19 | 19 | George Pearson Bridge (Nanaimo) | Campbell River Bridge (Campbell River) | 156.13 |
| 20 | 19 | Campbell River Bridge (Campbell River) | Ferry Toll Booth (Bear Cove) | 235.28 |
|  |  | Highway 99 - Vancouver to Cache Creek Corridor |  | 307.32 |
| 2122 | 99 | Intersection Hwy 99/1 (Horseshoe Bay) | Whistler Road (Whistler) | 98.54 |
|  | 99 | Whistler Road (Whistler) | Intersection Hwy $99 / 97$ (North of Cache Creek) | 208.78 |
|  | Highway 37-Terrace to Yukon Corridor |  |  | 724.97 |
| 23 | 37 | Intersection Hwy 37/16 (South of Kitwanga) | Yukon border | 724.97 |

### 3.0 Performance Measurement and Problem Definition

### 3.1 Provincial Objectives

Performance measures reflect the objectives they are trying to gauge. The higher level objectives for the Provincial Highway System flow from the MoTH mission statement :
"To facilitate the safe and efficient movement of people and goods, and the realization of government objectives by planning delivering and operating British Columbia's highways and infrastructure, and, by licensing and regulating it's users"

From the mission statement, the objectives which apply to the Provincial Highway System include:

- A safe highway system
- Efficient movement of people and goods
- Realization of other Government Objectives

Other Government Objectives outlined in the BC21 document "Going Places" ${ }^{1}$ and "British Columbia Provincial Highway Plan - Strategy Component"" include:

Infrastructure Maintain the infrastructure in a state of readiness to provide service,

Condition

Environmental Sustainability

Development

Development

Equity $\quad$ Fair distribution of costs and benefits
Efficiency Allocation of resources to get the maximum output

Economic Contribute to the establishment and ongoing support of appropriate

Community A highway system consistent with and supportive of economic and without running down the assets

Avoid impacts that could threaten the viability or function of the ecosystem economic activities in the Province. land use goals

[^0]
### 3.2 Objectives for the Provincial Highway Plan

Translating Provincial objectives into objectives for the Provincial Highway Plan, the plan should:

1. Maintain mobility and safety in the system and
2. Protect the investment in Highway infrastructure

To implement these objectives, the plan should include:
a) Problem identification - areas in the Provincial Highway System with the poorest performance
b) Problem definition - General causes of the problems
c) General solutions based on available corridor/systems plans or on more generic solutions consistent with the level of detail available
d) Benefit cost/MAE analysis of the alternatives as a tool for allocating a fixed budget across the Province

The objective of this phase of the PHP is to address the problem identification and problem definition steps above.

### 3.3 General Approach

## Problem Identification:

Problem identification is distinct from problem definition. Low travel speed for example, identifies a problem. The reason (problem definition) may be low capacity, poor geometry, high access density etc. but the problem perceived by the highway user remains the same.... travel speed. Problems are identified using Performance Measures to determine if and where there is a problem. The measures used should be simple and applied on an equal basis across the Provincial Network.

Regardless of the underlying cause, deficient highway performance will manifest itself in four ways:

1. low travel speed
traffic delays usually due to congestion or development
2. high accident rate accident frequency is above average
3. poor reliability frequent highway closures
4. deteriorating infrastructure

Bridges or pavement in need of repair

For each performance measure a convention of "Good", "Fair" or "Poor" is defined and used in the analysis. Poor ratings do not necessarily mean that action must be taken. A poor rating only identifies a need. The decision to take action depends on affordability, cost/ benefit and Multiple Account arguments.

## Problem Definition:

Problem definition looks at the underlying causes in order to:

- identify general types of solutions
- supply the data needed to generate and analyze solutions at the PHP level.

Problem definition is discussed in the following sections in the context of each performance measure - travel speed, safety, reliability and infrastructure.

The problem definition data needed to support a Provincial highway plan is more general in nature than for a corridor plan. A provincial highway plan might simply address the number of signals in a corridor, while a corridor plan might look at intersection capacity analysis and signal progression.

Even the general nature of data needed to support problem definition at the PHP level can absorb a disproportionate amount of effort if it is applied across the entire highway system. The approach in the PHP is to collect the data needed to identify the problem areas first (travel speed, safety, reliability, infrastructure condition). Once the problem areas are identified, further data collection is limited to the identified problem areas. This reduces the amount of data collected about highway segments for which there is no problem.

Benefit cost and MAE are not normally done at the Provincial or system level. They are done at the project level and then summed to provide the Provincial or system level assessment

### 3.4 Travel Speed

Travel speed is the first performance measure. Travel speed represents the highway user's perspective since it includes all stops or delays related to traffic operation. It is not the, design or posted speed of the highway. Travel speeds measured over the length of a corridor show how the highway performs overall. Speeds measured over a segment will identify individual problem areas which may be causing the poor corridor performance.

### 3.4.1 Corridor Travel Speeds

Corridor travel speeds show how the highway performs over long distance trips. Proposed rating criteria for highway corridors are stratified by Strategic Class (primary, secondary) instead of Functional Class (Freeway, expressway, arterial). A corridor often includes more than one service class, but the strategic class remains constant, reflecting the inter-regional role of a highway. The strategic class also determines what level of service should be provided at the corridor level while service class defines how that level of service is delivered for a given traffic volume.

## Problem Identification for Corridor Speeds:

The goal is to ensure adequate performance at the corridor level not just the segment level. Individual segments in a corridor may be performing adequately for their given service class, but if for example, there are too many urban segments in what is primarily a rural corridor, the corridor as a whole cannot meet its mobility goals.

The speed measured, should represent the average travel speed of a continuous trip through the corridor during the typical peak period of the year, such as a summer weekday.

The issue of what constitutes an adequate corridor speed is subjective. The National Highway Policy recommends a $90 \mathrm{~km} / \mathrm{hr}$ minimum operating speed. This is desirable but is not a reasonable short term goal in B.C. since it would imply building about 60 bypasses around communities on the National Highway System ${ }^{3}$ in order to maintain $90 \mathrm{~km} / \mathrm{h}$.

Rural primary corridors: This includes all primary highways outside the Lower Mainland. A reasonable interim goal is to achieve an overall travel speed of $80 \mathrm{~km} / \mathrm{hr}$ including $90 \mathrm{~km} / \mathrm{hr}$ operation outside of built up areas within the rural corridor.

Rural Secondary Corridors: The corridor speed criteria of $75 \mathrm{~km} / \mathrm{h}$ assumes the corridor is comsits entirely of rural arterial segments.

Proposed Corridor Criteria

|  | Good | Fair | Poor |
| :---: | :---: | :---: | :---: |
| Strategic Class | Peak Period Corridor Travel Speed (km/hr) |  |  |
| RP (Rural Primary) | $\begin{aligned} & >\text { or } \\ & =80 \end{aligned}$ | $\begin{gathered} 75 \text { to } \\ 79 \end{gathered}$ | $<75$ |
| RS (Rural Secondary) | $\begin{aligned} & >\text { or } \\ & =75 \end{aligned}$ | $\begin{gathered} 70 \text { to } \\ 74 \end{gathered}$ | <70 |
| UP (Urban Primary) | 71 | $\begin{gathered} 61 \text { to } \\ 66 \\ \hline \end{gathered}$ | <66 |
| US (Urban Secondary) | 37 | $\begin{gathered} 36 \text { to } \\ 32 \\ \hline \end{gathered}$ | <32 |

Urban primary corridors: This includes highways 1, 7, 91 and 99 in the Lower Mainland. The travel speed criteria is $71 \mathrm{~km} / \mathrm{h}$ which assumes the corridor is made up of $75 \%$ urban freeway segments at $80 \mathrm{~km} / \mathrm{h}$ and $25 \%$ urban expressway segments at $40 \mathrm{~km} / \mathrm{h}$.

Urban secondary corridors: The speed criteria of $37 \mathrm{~km} / \mathrm{h}$ assumes the corridor is made up of $50 \%$ expressway segments at $45 \mathrm{~km} / \mathrm{hr}$ and $50 \%$ arterial segments at $30 \mathrm{~km} / \mathrm{hr}$

## Problem Definition for Corridor Speeds:

At the PHP level, problem definition requires enough information to identify the general causes of low travel speed in a corridor. This may include:

[^1]|  | Cause of Low Travel Speed |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Data Requirement | v/c <br> Ratio | Access | Signals | Geometry | Passing <br> Oppor- <br> tunity |
| AADT, SADT | $\checkmark$ |  |  |  |  |
| DHV | $\checkmark$ |  |  |  | $\checkmark$ |
| \% trucks | $\checkmark$ |  |  |  |  |
| Laning | $\checkmark$ |  |  |  |  |
| Access Locations |  | $\checkmark$ |  |  |  |
| Access management |  | $\checkmark$ |  |  |  |
| Posted Speed |  | $\checkmark$ |  |  |  |
| Signal Location |  |  | $\checkmark$ |  |  |
| Curvature |  |  |  | $\checkmark$ |  |
| Grade |  |  |  | $\checkmark$ |  |
| Terrain | $\checkmark$ |  |  |  | $\checkmark$ |
| Passing Lane <br> Location | $\checkmark$ |  |  |  | $\checkmark$ |

### 3.4.2 Segment Travel Speeds

## Problem Identification for Segment Speeds:

The peak period speed is used to identify problem areas since declining peak period speeds are usually the first sign of an approaching problem. For each segment, the peak period speed is the average speed on a segment during typical high demand periods. On the TCH for example, this would typically be a summer mid-day travel speed.

Segment speed criteria are stratified by urban and rural classifications. The urban classification is designated using the Functional Classification Manual ${ }^{4}$, which defines urban as a population center greater than 5,000 . For the PHP, the limits of the urban area are defined by the changes in posted speed which occur at the approach to the developed area. Municipalities with less than 5,000 remain classified as rural even if they have reduced speed zones.

## Urban Travel Speed Criteria

Travel speed performance on urban segments is rated using criteria from the Functional Classification Study and the Highway Capacity Manual. The speed being rated is the typical peak period travel speed on the segment. The ratings proposed for the 1997 PHP are revised downwards from the 1995 PHP analysis since the current performance measure is focusing on peak period speeds more than off peak speeds.

[^2]
## Urban Segments

|  | Recommended Criteria |  |  |  | B.C. Functional |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Service | Good | Fair | Poor | Highway Capacity |  |
| Class | $>$ or $=$ | $<$ | $<$ | Classification Manual | Manual |

Peak Period Travel Speed
( $\mathrm{km} / \mathrm{hr}$ )

| UF | 80 | 80 | 75 | minimum is $75 \mathrm{~km} / \mathrm{hr}$ <br> and C/D interface | Depends on Design <br> Speed |
| :--- | :---: | :---: | :---: | :--- | :--- |
| UE | 45 | 45 | 40 | minimum is $40 \mathrm{~km} / \mathrm{hr}$ <br> and C/D interface | Arterial LOS <br> C/D $=35 \mathrm{~km} / \mathrm{hr}$ |
| UA | 30 | 30 | 25 | minimum 20 to 40 <br> $\mathrm{km} / \mathrm{hr}$ and C/D interface | Arterial LOS <br> $\mathrm{C} / \mathrm{D}=35 \mathrm{~km} / \mathrm{hr}$ <br> $\mathrm{D} / \mathrm{E}=27 \mathrm{~km} / \mathrm{h}$ |

*The LOS interfaces shown in this column were adopted from the ASSHTO Green Book (1992). Caution must be excercised when using these as deficiency indicaotors because:

1. The definitive justification for improvements comes from Multiple Accounts Evaluation (including benefit cost analysis), discussed later in this report
2. Planning and project funding is likely to be limited for the foreseeable future and the case has been made that a "finer screen" should be used for mobility problem identification, which would help focus resources on compraratively worse areas.
It is possible that the mobility deficiency criterion could change to LOS D/E for urban highways and rural 4 lane highways, and to LOS C/D for rural 2 lane highways, for regularly occuring peaks.

## Rural Travel Speed Criteria

The performance measure for speed on rural highway segments also uses the peak period travel speeds. The criteria for rating speed on rural highway segments were based on the cumulative distribution of rural travel speeds from the 1995 PHP data in exhibits $3.2,3.3$ and 3.4 and are consistent with the previous analysis. Typically, the distribution for each service class displays a knee in the curve, below which the travel speeds drop off rapidly. This generally indicates a failure of some kind and is a good place to intervene, so speeds below the knee are used to define the "poor" speed rating. Speeds in the vicinity of the knee ( $5 \mathrm{~km} / \mathrm{h}$ above the poor zone) define the "fair" rating and speeds above the knee are "good". The curves for rural freeway and rural expressway should be treated with caution since the sample size is limited. These speed ratings are more judgmental than statistical.

Rural Segments

| Service <br> Class | Good | Fair <br> $<$ | Poor <br> $<$ | Provincial <br> Distribution <br> from 1995 <br> PHP | 1994 Highway <br> Capacity Manual <br> Level of Service <br> Interface and Speed |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Peak Period Travel <br> Speed (km/hr) |  |  | In |  |
| RF | $>$ or <br> $=95$ | 90 to <br> 94 | $<90$ | Exhibit 3.2 | C/D $=89$ to $110 \mathrm{~km} / \mathrm{hr}$ |
| RE | $>$ or <br> $=80$ | 75 to <br> 79 | $<75$ | Exhibit 3.3 | $\mathrm{C} / \mathrm{D}=72$ to $93 \mathrm{~km} / \mathrm{hr}$ |
| RA | $>$ or <br> $=75$ | 70 to <br> 74 | $<70$ | Exhibit 3.4 | $\mathrm{C} / \mathrm{D}=80.5 \mathrm{~km} / \mathrm{hr}$ <br> $\mathrm{D} / \mathrm{E}=72.5 \mathrm{~km} / \mathrm{hr}$ |

Exhibit 3.2
Cumulative Veh-Km of Travel vs Speed
RURAL FREEWAYS

## Exhibit 3.3

Cumulative Veh-Km of Travel vs Speed RURAL EXPRESSWAY

Exhibit 3.4
Cumulative Veh-Km of Travel vs Speed RURAL ARTERIAL HIGHWAYS

## Problem Definition:

If a travel speed is identified as poor, then further information is needed to define and analyze the problem. This is the same as the information collected under problem definition for corridor speeds, if it has not already been collected.

In addition, benefit cost analysis will require some additional travel speed information for use in benefit cost analysis. The minimum is the typical travel speed and traffic volume during the peak and off peak periods. This allows the analyst to adjust the default speed volume curve generated by benefit cost models to reflect the actual speeds in

Additional Data Requirements

| Peak Period Travel Speed | $\checkmark$ |
| :--- | :---: |
| Peak period traffic volume | $\checkmark$ |
| Off peak travel speed | $\checkmark$ |
| Off peak traffic volume | $\checkmark$ | the segment. This is recommended since benefit cost models using speed calculations from the highway capacity manual often do not adequately represent actual conditions. The speed measured in the field should be a space mean speed using a floating car technique. This involves driving the segment at the average traffic speed in order to get an average travel speed over the segment. It is different from the spot mean speed which measures speed at a point using radar or a traffic counter/classifier for example.

### 3.5 Safety

## Problem Identification:

The proposed performance measure uses the critical accident rate for a highway segment or major corridor. Critical rate is a function of average accident rate and exposure measured as vehicle-km. The critical rate for a highway section is calculated as:

$$
\mathrm{CR}=\mathrm{AR}+1.645 \mathrm{X} \mathrm{SQRT}(\mathrm{AR} / \mathrm{MVK})+1 /(2 \mathrm{X} \mathrm{MVK})
$$

Where: $\mathrm{CR}=$ critical accident rate for a given highway section
$A R=$ average accident rate for the highway service class on the section
MVK = million veh-km for a the given highway section
At the segment level, critical accident rate is calculated using the average accident rates from Highway Safety Branch by service class ${ }^{5}$

| Service <br> Class | Average Rate <br> $(\mathrm{a} / \mathrm{mvk})$ |  |
| :--- | :--- | :--- |
|  |  |  |
| UA | 1.4 | Urban Arterial |
| UE | 1.5 | Urban Expressway |
| UF | 1.0 | Urban Freeway |

[^3]| RA | 0.7 | Rural Arterial |
| :--- | :--- | :--- |
| RE | 1.2 | Rural Expressway |
| RF | 0.6 | Rural Freeway |

At the corridor level, critical accident rate is calculated using the average accident rates by Strategic Class. These are summarized from the 1995 PHP data.

| UP | 0.9 | Urban Primary |
| :--- | :--- | :--- |
| US | 1.1 | Urban Secondary |
| RP | 0.7 | Rural Primary |
| RS | 0.9 | Rural Secondary |

Differences between urban rates by strategic class and service class may stem from how the roads were classified. The proposed criteria are based on the critical accident rate:

Good: accident rate is less than the critical rate
Fair: accident rate is greater than or equal to the critical rate, but less than 1.5 X the critical rate

Poor: accident rate is equal to or greater than 1.5 X the critical rate

## Problem Definition:

Investigating the cause of high accident rates is normally done at the corridor or project level through a micro analysis of accident data or a safety audit. At the Provincial planning level, micro analysis is not practical for the entire highway system. The general approach is to address a limited number of accident factors, only in high accident segments or locations and give some general guidance on the nature of the problem.

The data collected should be include accident frequency and exposure data needed for benefit cost/ MAE analysis and accident factors to define the nature of the accidents on the highway corridor or segments. This includes:

- Number of accidents
- Number fatal accidents (not number of fatalities)
- Number of injury accidents
- Number of Property Damage Only (PDO) accidents
- AADT
- Section length if applicable
- Limited data from the HSIS database

Guidelines on applying the accident frequency data are in chapter 5 on Benefit Cost Analysis.

The underlying problems related to higher than normal accident rates are usually a combination of factors. Highway Safety Branch gives the following distribution for numbered highways in the Province.

| Contributing factors | $\%$ |
| :--- | :---: |
| Human Action | $24.6 \%$ |
| Human Condition | $20.5 \%$ |
| Animal | $11.7 \%$ |
| Environmental Condition | $8.2 \%$ |
| Vehicle Condition | $2.2 \%$ |
| Road Factor | $1.8 \%$ |
| Unknown Factor | $31.0 \%$ |

For the PHP analysis, these contributing factors are expanded into the 8 causal factors below. The data needed to support these causal factors comes form the HSIS database and not from the PHP database. The HSIS database is a compilation of the Police accident report forms (MV104 form).

Causal Factors and Supporting Data
for High Accident Locations

|  | Causal factors |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Supporting Data Required * | Wild Animals | Weather | Driver Condition | Veh Condition | Access | Signals | Geom etry | Congestion Points |
| Type of accident collision | $\checkmark$ |  |  |  |  |  |  |  |
| Apparent contributing factors |  | $\checkmark$ | $\checkmark$ | $\checkmark$ |  |  |  |  |
| Accident Location |  |  |  |  | $\checkmark$ |  |  |  |
| Traffic Control |  |  |  |  |  | $\checkmark$ |  |  |
| Roadway Character |  |  |  |  |  |  | $\checkmark$ |  |
| Precollision action |  |  |  |  | $\checkmark$ |  |  | $\checkmark$ |
| Roadway Surface Condition |  | $\checkmark$ |  |  |  |  |  |  |
| Weather Conditions |  | 7 |  |  |  |  |  |  |

* Data field names correspond to selected field names on the Police MV104 accident report form. MV104 reports are used to compile the HSIS database.

The causal factors point toward the general solutions appropriate to the Provincial planning level, such as educational, wildlife management, geometric, enforcement or access management actions.

### 3.6 Reliability

## Problem Identification:

District highway offices report highway closure data by fax to the communications center in Burnaby giving the time, duration, cause and general location of the closure. Two years of record covering the Provincial numbered highways showed the following data:

| Time period covered | 1995 and 1996 |
| :--- | :--- |
| Total Number of Closures | 394 |
| Average rate of closures | $5.23 \mathrm{hrs} / \mathrm{km} / \mathrm{yr}$ |

This data includes a storm lasting several days at the end of 1996 which produced widespread extended highway closures.

Closures can either be point closures such as a motor vehicle accident or closures covering an extended area due to weather conditions. In either case, a closure is assumed to impact an extended length of highway. For this analysis the length of highway impacted by a closure is defined as the length of the lki segment ( 1995 LKI) in which the closure occurs. This is used to generate the average closure $/ \mathrm{km} /$ year used in rating highway closure frequency.

The general approach uses the critical closure rate calculated in the same manner as the critical accident rate used by Highway Safety Branch to identify locations with high accident frequency.

The critical closure rate is a statistical function based on average closure rate expressed as hours of closure $/ \mathrm{km} / \mathrm{yr}$. Exposure is defined as kilometers of highway instead of vehiclekilometers of travel since highway closures are often unrelated to traffic volume. The critical rate for any highway section is calculated as:
$\mathrm{CR}=\mathrm{AR}+1.645 \mathrm{XSQRT}(\mathrm{AR} / \mathrm{K})+1 /(2 \mathrm{X} \mathrm{K})$
Where: $\mathrm{CR}=$ critical closure rate for a given highway section in hrs. of closure $/ \mathrm{km} / \mathrm{yr}$
$\mathrm{AR}=$ average closure rate on Provincial numbered highways ( $5.23 \mathrm{hrs} / \mathrm{km} / \mathrm{yr}$ )
$\mathrm{K}=\mathrm{km}$ of highway in a the section for which the critical rate is to be measured
The proposed criteria for rating highway closures are based on the critical accident rate:

| Good: | closure rate is less than or equal to the critical rate |
| :--- | :--- |
| Fair: | closure rate is greater than the critical rate, but less than or equal to 1.5 X the <br> critical rate |
| Poor: | closure rate is equal to or greater than 1.5 X the critical rate |

Problem identification would benefit from a standard method of reporting highway closures. The present method relies on written descriptions faxed to the communications center which must be entered manually into a database.

## Problem Definition:

Problem definition includes characterizing the frequency and causes of closures to help define corrective actions or programs at the Provincial Level., the reasons and number of occurrences are listed here, based on the $1995+1996$ data.

| MVA | 158 |
| :--- | :---: |
| Weather Conditions | 56 |
| Truck Accident (excl. <br> log/lumber) | 36 |
| Avalanche/Hazard/Control | 35 |
| Rock/Mud Slide | 27 |
| Lumber/Log Truck Spill | 15 |
| Wash Out/Flood | 14 |
| Other | 11 |
| Vehicle Recovery | 10 |
| Fire | 7 |
| Hazardous Materials | 6 |
| Downed Power Lines | 6 |
| Trucks Without Chains | 3 |
| Fallen Trees | 3 |
| Scheduled/Construction | 2 |
| Emergency Repairs | 1 |
| Airplane Crash | 1 |
| Rock Work | 1 |
| Train Breakdown | 1 |
| Total | 393 |

### 3.7 Pavement Condition

## Problem Identification:

Pavement Quality Index (PQI) is used in B.C. to measure overall pavement condition. It is a composite measure derived from the Pavement Distress Index (PDI) and the Ride Comfort Index (RCI) as $\mathrm{PQI}=40 \%(\mathrm{PDI})+60 \%(\mathrm{RCI})$.

PDI is measured on a scale of 1 to 10 with 10 rated very good. PDI measures the type and degree of distress such as cracking or deformation and helps to evaluate the causes of
pavement failure. Condition is surveyed every two years on group I (primary) highways and every three years on group II (secondary) highways.
$R C I$ is a measure of riding comfort experienced by the road user as they travel over the road surface. Continuous profile roughness measurements are collected for each wheel-path using either ultra-sonic or laser based automated roughness profile measuring systems. RCI is measured on a scale of 1 to 10 with 10 rated as very good.

The PQI reference system is:

| PQI Less than <br> or Equal to: | Rating | Definition |
| :---: | :---: | :--- |
| 10.0 | Very Good | Like new with very few defects |
| 8.5 | Good | Many years of serviceable life remaining |
| 7.0 | Fair | Close to or needs some type of rehabilitation |
| 5.0 | Poor | Should have been rehabilitated within the last few years <br> with potential for accelerated deterioration |
| 3.5 | Very Poor | Should have been rehabilitated many years ago and is <br> very deteriorated |

PQI is currently available for 1995 for all the Primary Highways. 1996 data will be available for Secondary Highways in Region 2,3,4 and 5 in March. PQI is reported by Highway Engineering in 1 km to 5 km increments using HLRP (Highway Locational Referencing Project) for location

Remaining pavement life was suggested but is not used as the measure of need since there is no formal remaining life data collected. Remaining life is a function of traffic, environmental, rehabilitation and maintenance conditions and varies with individual sites. Instead of estimating remaining life at a given year, the approach is to estimate pavement condition and backlog for a given year. Future pavement condition can be estimated based on age and traffic.

Backlog is the total kilometers of highway that would be rehabilitated under normal pavement management practices. PQI is commonly used by highway agencies as the basis for determining backlog. A trigger value is defined and all sections exceeding this limit represent the current deficiency. A trigger value of $\mathrm{PQI}=6.4$ is used for the PHP analysis. This takes into account both the pavement distress and roughness condition thresholds in which surface rehabilitation is first warranted.

The proposed performance measure for the Provincial Highway Plan is based on the PQI.

| Description | PQI |
| :--- | :---: |
| does not yet need resurfacing | $>6.4$ |
| needs resurfacing now $<$ or $=6.4$ <br> and $>5$  |  |
| Should have been rehabilitated <br> within the last few years. Has <br> potential for accelerated <br> deterioration | $<$ or $=5$ |

## Problem Definition:

Pavements are normally designed for a 15 year life before an overlay is required. For a given thickness-design and subgrade, life is governed by environmental conditions and traffic loading. Environmental conditions affect pavement life through freeze thaw conditions. thermal cracking and loss of subgrade support during spring thaw.

Traffic loading is the expected number of equivalent single axle loads (ESALs) over the life of the pavement ( 1 ESAL $=8,172 \mathrm{~kg}$ ). If either the number of trucks or the average axle loading increase above those assumed for the original design, then the ESALSs increase and pavement life is shortened accordingly.

At the Provincial level, truck volume relates to mode choice and economic conditions and is generally beyond the scope of a Provincial highway plan to influence:

- mode choice (road vs rail) - railways are concentrating on long distance, bulk transportation and are abandoning branch line service. Solutions may range from supporting short line operation or equitable tax treatment of railways compared to highway.
- Just-in-time Delivery - The higher variability in rail delivery time favours a mode shift to truck.
- Industrial consolidation - Mills and industries closing marginal plants end up shipping raw materials and product further.
- Road Pricing - While trucks pay most or all of the direct costs they impose on the highway system through road taxes, highway traffic in general (both cars and trucks) does not pay the external costs of highway transportation. More effective road pricing would internalize some of these external costs shifting more traffic to rail ${ }^{6}$.

This leaves axle loading as the issue under the most direct control of the Province. Overloading usually stems from short haul construction or resource traffic. Long haul traffic

[^4]generally traverses several weigh stations en route and is unlikely to be overloaded. Provincial strategies for enforcing legal axle loads include ${ }^{7}$ :

- Short haul traffic - Increase mobile enforcement to replace static scales which have limited hours of operation or are not intercepting the short haul traffic.
- Long haul traffic - provide full service inspection stations with 24 hour operation and encourage weigh-in-motion (WIM) and automated vehicle identification (AVI) technologies to reduce delay.

### 3.8 Bridge and Major Structure Rehabilitation

Bridge rehabilitation includes repairs, upgrades and replacements.

| Repairs: | to extend life, reduce maintenance <br> cost or improve safety. |
| :--- | :--- |
| Upgrades: | to improve a structure to a higher <br> standard (i.e. widening). |
| Replacements: | when it is more cost effective than <br> repairs or upgrades |

The Provincial Highway Plan first identifies problems at the corridor level. If a corridor performs well overall, the strategy is to keep it that way through regular maintenance and rehabilitation to maintain safety and level of service. If a corridor exhibits poor level of service or safety performance, then the strategy is to identify the causes and propose general improvements or projects to address them.

In most cases, poor corridor performance is caused by a range of problems which point to a program of improvements as part of a corridor plan. Depending on the nature of the corridor deficiency, there are many possible actions which could be included in the program. As they relate to structures, these actions may include:

| Corridor <br> Deficiency | Possible Causes Related to <br> Structures | Possible Actions Related to <br> Structures |
| :---: | :--- | :--- |
| Low Travel <br> Speed | Low Bridge Capacity <br> Poor approach alignment | Added bridge capacity. <br> Realign approaches or bridge. |
| High Accident <br> Rate | Poor approach or bridge alignment <br> Poor end treatment <br> Substandard width* | Realign approaches or bridge. <br> Widen or replace. |
| Poor Reliability <br> (closures) | Seismic rating is potentially a cause <br> Bridge Condition | Seismic Rehabilitation <br> New bridge with seismic standard <br> Replace or rehabilitate |
| Deteriorating <br> Infrastracture/ <br> High Maint. Cost | Bridge Condition | Replace or rehabilitate |
| Load Restriction | Bridge Condition | Replace or upgrade |

[^5]|  | Low original live load design <br> standard <br> Increasing truck weight |  |
| :---: | :--- | :--- |
| Restricted Vert. <br> Clearance | Poor service design | Replace or upgrade |
| None | Structures performing adequately <br> Deficiencies not significant at <br> corridor level | Regular maintenance and <br> rehabilitation. |

* Substandard bridge width in relation to highway class is considered as a cause of safety or travel speed problems. It is not considered as a problem in itself.
From the Provincial planning perspective, the need for action is high if there is:
- A high accident rate
- Poor bridge condition
- Poor travel speed in the corridor, attributable to low traffic capacity on a bridge.
- Detour or restrictions due to a bridge live load or clearance deficiency

While these criteria indicate a need, they do not necessarily mean action should be taken. Solutions depend on the underlying causes of the problems, proposed corridor plans and benefit cost arguments. At the PHP level, solutions are addressed in general terms only.

The following criteria are used to indicate the need. Safety performance is a concern for bridges but it is already captured as a separate performance and is not repeated as a criteria here. A bridge on the primary or secondary system is given an overall fair or poor rating if any of the criteria below are fair or poor.

| Measure | Good | Fair | Poor |
| :--- | :--- | :--- | :--- |
| Condition | $\mathrm{BCI}<$ or $=2.0$ | $2.0<\mathrm{BCI}>=3.0$ | $\mathrm{BCI}>3.0$ |
| Travel Speed | $\mathrm{v} / \mathrm{c}<=0.8$ | $0.8<\mathrm{v} / \mathrm{c}<=0.9$ | $\mathrm{v} / \mathrm{c}>0.9$ |
| Load <br> Restriction | none | $>\mathrm{or}=$ to 57 tonnes <br> and $<63.5$ tonnes | $<57$ tonnes |
| Dimensional <br> Restriction | none |  |  |

$\mathrm{AR}=$ bridge accident rate in accidents/million vehicles ( $\mathrm{a} / \mathrm{mv}$ )
$\mathrm{CR}=$ Critical accident rate for a bridge ( $\mathrm{a} / \mathrm{mv}$ )
$\mathrm{BCI}=$ Bridge Condition Index. BCI measures the overall bridge condition based on condition of the channel, substructure, superstructure and deck. This data is complied by regional Bridge Engineers.
$\mathbf{v} / \mathbf{c}=$ Volume to Capacity Ratio
Load Restriction - This is the maximum allowable gross vehicle weight (GVW) on the bridge. 63.5 tonnes is the legal GVW for an 8 axle B-train. A 6 axle Tractor semitrailer unit has a maximum 45 tonnes.

Dimensional Restrictions - Bridge cross section should generally be consistent with the cross section of the highway it serves. For rural arterial undivided highways the cross sections vary with the design hour volume. The standard for overhead clearance is 5.0 m .

| DHV | Lane <br> Width <br> $(\mathrm{m})$. | Shoulder <br> Width <br> $(\mathrm{m})$. |
| :---: | :---: | :---: |
| $<200$ | 3.6 | 1.5 |
| $<=450$ | 3.6 | 2.0 |
| $>450$ | 3.6 | 2.5 |

### 3.9 Seismic Needs

Seismic upgrading is reported separately from bridge rehabilitation since this issue is unique to bridges along the coast in zones of high seismic activity. Funding for seismic upgrading is generally considered separately from bridge replacement and rehabilitation programs. The purpose of the seismic retrofitting program is "to minimize loss of life and injury during earthquakes and to preserve important routes for use after earthquakes" ${ }^{8}$.

The Province is mapped into acceleration related seismic zones ranging from 0 (lowest) to 6 (highest). The retrofit program is reviewing about 470 bridges in seismic zones 2,3,4,5 and 6 of which an estimated 250 may require retrofitting. The highest priority bridges are those identified as part of lifeline or emergency routes.

## Lifeline route Bridges

The lifeline classification is assigned to major bridges based on SADT, bridge length and detour length. There are 16 lifeline structures in the Province of which 14 are considered vulnerable to damage and collapse and 2 are built to earthquake standards. The vulnerable bridges include 11 in the Lower Mainland plus the Agassiz-Rosedale and Okanagan Lake Bridges.

Emergency route bridges:
Region 1-corridors for emergency vehicles through the lower mainland, based on routes with minimum numbers of vulnerable bridges. Region 5- routes from Terrace to Prince Rupert and Kitimat Region 6- routes from Victoria to Swartz Bay, Colwood and Parksville.

For the PHP, a three tier rating scheme is proposed, consistent with criteria for other performance measures in the PHP.

| Priority | Lifeline or Emergency <br> Route Bridges | Other Bridges in <br> Seismic Zones |
| :--- | :--- | :--- |
| High | $\bullet$Not designed to <br> 1983 ASSHTO <br> seismic standard or, <br> Not retrofitted | None |
| Medium | $\bullet$ Partial retrofit |  |
| completed |  |  |$\quad$ None $|$| Low |
| :--- |
| Designed to 1983 <br> AASHTO seismic <br> standard or |
| Full retrofit <br> completed. |

[^6]
### 4.1 Introduction

At the Provincial Highway Plan level, traffic forecasts are used for:

- benefit cost analysis,
- timing of improvements,
- LOS analysis and
- greenhouse gas estimates for future years.

At the PHP level, a Provincial transportation model would be the preferred approach to forecast traffic volumes but one has not yet been developed. The approach in the PHP uses simpler linear regression models. On a given highway, the correlation is established between historical traffic and population'. The regression model is then used to predict future traffic, using population projections as the independent variable.

Transportation models offer more accurate population based forecasting and are useful for predicting diversion to other routes in a network. At the corridor level, such as Kamloops to the Alberta Border, the highway is a linear system with little opportunity for diversion and the advantages of a network model are limited mostly to forecasting. For the corridor level it is proposed not to use a network model until a Provincial model is available. Calibrating network models at the corridor level requires a large effort for a relatively small area. It is recommended that one Provincial model be developed rather than repeatedly calibrating smaller regional models.

The proposed approach at the corridor level is to forecast traffic using a population based regression model. At the PHP level the general approach is:

1. Select a representative permanent count station in the corridor.
2. Define the population areas which influence traffic growth at that count station.
3. Obtain historical population and traffic statistics
4. Calibrate historical traffic growth with population growth
5. Forecast traffic growth based on population forecasts
6. Translate the selected permanent count forecasts to the local area of interest
7. Calculate a design hour volume
[^7]
### 4.2 Select a Permanent Count Station

At the PHP level, only permanent count stations with 6 years of record or more are used to correlate population growth with traffic growth. Short counts are not used since the year to year variation is usually too high to correlate traffic with population in any meaningful way.

From Kamloops to Alberta, there are three permanent counter stations:
21-001 Monte Creek East of Kamloops 1965-1995
22-001 E. of Sicamous Since 1986 (short count only prior to 1986)
37-001 E of Golden since 1993
P21-001 has about 30 years of record and is used to correlate traffic with population.

### 4.3 Characterise Traffic Generation

Traffic generation on a section of highway is usually related to population growth in a defined area or zone served by the highway. Transportation models allow for many zones to be considered but in the absence of a calibrated Provincial model, traffic growth is characterized using a limited number of zones, in order to be manageable. For example, two zones can be defined; one influencing non-local traffic and the other local traffic:

## Non-Local Traffic

Non-Local traffic is defined here as through traffic with origin or destination outside the urban area (the Highway Classification Manual defines Urban areas as having population $>5,000$ ). Counter P21-1 is located at Monte Creek east of Kamloops and by this definition, reflects non-local traffic. As an inter-Provincial corridor, non-local traffic volumes on Highway 1 are strongly related to population growth in the Province as a whole so in this case, the population of BC is used as the independent variable correlated to traffic at this counter location. Historical and forecast population for local Health Areas are (will be) included as appendix B.

## Local Traffic

The local traffic component of a traffic count is defined here as traffic with origin or destination in the urban center where the counter is located. Since P21-1 lies outside of the Kamloops urban area, then it has no local traffic component.

Exhibit 4.1
SADT
Kamloops to Alberta

| Year | $21-1$ | Population |
| :--- | :--- | :--- |
|  |  |  |
| 1971 | 4,275 | $2,250,200$ |
| 1976 | 5,557 | $2,545,000$ |
| 1977 | 6,147 | $2,581,200$ |
| 1978 | 6,546 | $2,625,800$ |
| 1979 | 6,746 | $2,675,000$ |
| 1980 | 7,388 | $2,755,500$ |
| 1981 | 7,934 | $2,836,500$ |
| 1982 | 7,775 | $2,886,300$ |
| 1983 | 6,657 | $2,919,600$ |
| 1984 | 6,270 | $2,960,600$ |
| 1985 | 6,375 | $2,990,000$ |
| 1986 | 7,156 | $3,020,400$ |
| 1987 | 7,822 | $3,064,600$ |
| 1988 | 8,053 | $3,128,200$ |
| 1989 | 8,556 | $3,209,200$ |
| 1990 | 8,566 | $3,300,100$ |
| 1991 | 8,042 | $3,379,800$ |
| 1992 | 8,479 | $3,476,871$ |
| 1993 | 9,131 | $3,574,603$ |
| 1994 | 9,748 | $3,669,634$ |

### 4.4 Historical Population and Traffic Statistics

Historical population data are available for 1971 and 1976 through to 1994. The counter data goes back further but there is no matching population record so it is not used.

### 4.5 Correlate Historical Traffic and Population

A linear regression using population as the independent variable and AADT as the dependent variable may be done using any spreadsheet software. The results for this regression are:

|  | Regression Output: |
| :--- | ---: |
| Constant | -2120 |
| Std Err of AADT Estimate | 600 |
| Coeff. of Correlation R | 0.80 |
| No. of Observations | 20 |
| Degrees of Freedom | 18 |
| Population Coefficient | 0.00317 |
| Std Err of Coef. | 0.00037 |

The regression formula for projecting AADT at counter P21-1 uses only the BC population as the independent variable and is:

$$
\text { AADT }=.00317 \times \text { BC Population }-2,120
$$

### 4.6 Forecast Future Traffic

Using this regression formula the planning volumes at P21-1 are shown here.

|  | Year | BC <br> Population | P21-1 <br> AADT | Growth |
| :--- | :---: | :---: | :---: | :---: |
| Data Year | 1994 | $3,669,534$ | 9,748 | 1.000 |
| Base Year | 1997 | $3,945,233$ | 10,380 | 1.065 |
| Short Term Horizon | 2002 | $4,338,970$ | 11,635 | 1.194 |
| Medium Term | 2012 | $5,109,720$ | 14,069 | 1.443 |
| Long Term | 2022 | $5,860,999$ | 16,450 | 1.688 |

Annual traffic growth from the base year to the 25 year horizon averages $2.3 \%$ linear (or $1.86 \%$ compound) growth. The historical and projected traffic and AADT are illustrated below.

Exhibit 4.2

## B.C. Population and AADT on TCH

[^8]Typical problems encountered with this method are:

## Short Time Series

It is desirable to have about 10 years of record to establish a reasonable correlation between population and traffic. The minimum used is 6 years. A short time series usually gives a poor correlation.

## Poor Correlation:

Where population density or traffic volume is low or the historical time series is short, the correlation between traffic and population may be poor (a cutoff of $\mathbf{R}^{2}=.60$ is used as a minimum). If the correlation is poor, then future traffic is simply estimated to grow in the same proportion as future population, without regard to the historical correlation. In other words if the characteristic population grows at $2 \%$ then the traffic also grows at $2 \%$.

### 4.7 Translate to the Local area

As an example, project the traffic in Revelstoke. Relevant counter data includes:

| Counter <br> Number | Location | SADT | AADT |
| :--- | :--- | :--- | :--- |
| Permanent Counts    <br>  0.2 km east of Gorge Creek Bridge <br> at Craigellachie historical site. West <br> of Revelstoke 9,645 5,255 <br> P37-1 2.5 km east of route 95, east of <br> Golden 8,407 4,147 <br> P21-1 4.7 km west of Route 97, Monte <br> Creek, East of Kamloops 13,987 9,748 <br> Short Counts    <br> $38-001$ west end of the Columbia River <br> Bridge, in Revelstoke 12,400 $6,200^{*}$ <br> $38-004$ 4.0 km east or route 23, east of <br> Revelstoke 8,800 $4,400^{*}$ |  |  |  |

* AADT for the short counts is estimated as .50 x SADT based on the permanent count data from P22-1 and P37-1

## Non-local Traffic

Non-local traffic in Revelstoke is assumed to be 4,400 AADT or 8,800 SADT from counter 38-004 which measures traffic outside of Revelstoke to the east. It is assumed to grow at the rate defined by counter P21-1:

|  | Year | AADT | Growth |
| :--- | :---: | :---: | :---: |
| Data Year | 1994 | 4400 | 1.000 |
| Base Year $^{1}$ | 1997 | 4686 | 1.065 |
| Short Term Horizon | 2004 | 5474 | 1.244 |
| Medium Term | 2012 | 6349 | 1.443 |
| Long Term | 2022 | 7427 | 1.688 |

## Local Traffic

Total traffic on Highway 1 in Revelstoke is estimated to be 6,200 AADT from counter 38-001. Subtracting the non-local component 4,400 leaves a local component of 1,800 AADT. Local traffic is assumed to grow in proportion to the local Revelstoke population (Local Health Area 19):

|  | Year | Population <br> Revelstoke | Local <br> AADT |
| :--- | :--- | :--- | :--- |
| Data Year | 1994 | 8,862 | 1,800 |
| Base Year | 1997 | 9,029 | 1,834 |
| Short Term Horizon | 2004 | 9,401 | 1,909 |
| Medium Term | 2012 | 9,471 | 1,924 |
| Long Term | 2022 | 9023 | 1,833 |

Total traffic in Revelstoke is the sum of local and non-local:

|  | Year | AADT |
| :--- | :---: | :---: |
| Data Year | 1994 | 6,200 |
| Base Year ${ }^{12}$ | 1997 | 6,520 |
| Short Term Horizon | 2004 | 7,383 |
| Medium Term | 2012 | 8,273 |
| Long Term | 2022 | 9,260 |

[^9]
### 4.8 Design Hour Volume

The capacity needed to provide a given level of service, is estimated using the design hour volume (DHV). At the corridor planning level, the normal approach is to take peak hour traffic counts and use these as the DHV for level of service analysis. At the PHP level this is not possible, so DHV is estimated using three formulas:

| Type of <br> Traffic | DHV |
| :---: | :---: |
| Urban | $=30+.09 \times$ AADT |
| Rural | $=100+.11 \times$ AADT |
| Recreational | $=250+.13 \times$ AADT |

In Revelstoke for example, if peak hour counts were not available, then an estimate of DHV could be made using these formulae. Even though Revelstoke is classified as "urban" (population $>5,000$ ) most of the traffic is rural or through traffic.

Using the equation for estimating DHV for rural traffic (DHV $=100+$ . 11 AADT ) gives the following DHV's:

| Horizon | Year | AADT | DHV |
| :--- | :---: | :---: | :---: |
| Data Year | 1994 | 6,200 | 782 |
| Base Year | 1997 | 6,519 | 817 |
| Short Term Horizon | 2004 | 7,383 | 912 |
| Medium Term | 2012 | 8,274 | 1,010 |
| Long Term | 2022 | 9,258 | 1,118 |

The general formulae are derived from approximately 300 permanent count stations with an AADT over 500 in BC for 1993 shown below.

Exhibit 4.3

The urban, rural and recreational lines are defined subjectively in relation to the observed data. The observed data above is the 150 th highest volume of the year (HV150) for each count station and represents the normal daily peaks during the peak season, rather than the 30th hour volume. ${ }^{13}$

These DHV formulae are consistent with the 1995 PHP but allow for some variation in the K factor ( $=$ DHV/AADT) over the planning period as AADT increases. This is because growth in AADT is often the result of increased travel during off peak hours or seasons rather than peak periods which means DHV does not grow as fast as AADT. The assumption that DHV grows at the same rate as AADT would tend to overstate future capacity requirements.

For information purposes, some typical counter profiles are shown below:

|  | Recreational | Rural | Suburban | Urban |
| :--- | :--- | :--- | :--- | :--- |
| Counter | P15-3 | P21-1 | P17-4 | P15-2 |
| Highway | Hwy 99 | Hwy 1 | Rte 1 | Hwy 1 |
| Location | North of | at Hwy 97 | Bradner Rdin | 2nd Narrows |
|  | Squamish | Monte Creek | Matsqui | Bridge |
| K factor $(150 \mathrm{HV})$ | .16 | .12 | .09 | .10 |
| AADT | 8,063 | 13,988 | 61,348 | 112,030 |
| DHV | 1,370 | 1,679 | 5,521 | 11,203 |

Exhibit 4.4
The 200 highest hours from these count stations are profiled here

[^10]
### 5.1 Introduction

The financial and customer service accounts for multiple account evaluation come from benefit cost analysis. The costs are the financial account and the benefits are the customer service account.

In benefit cost analysis, the costs represent the incremental increase in capital and maintenance costs to the infrastructure providers while the benefits are the incremental reductions in time, accident and vehicle operating costs experienced by the highway user as a result of the proposed project. Benefits and costs are discounted over the life of the project to a single present value. Who pays and who benefits are not considered. Cost shared amounts for example, should not be subtracted from costs.

The two economic performance measures most commonly used from $B / C$ analysis for selecting projects are $B / C$ and NPV.

| Measure | Definition |
| :--- | :--- |
| Benefit Cost Ratio <br> (B/C ratio) | Present Value of <br> Benefits/Present Value of <br> Costs |
| Net Present Value <br> (NPV) | Present Value of Benefits - <br> Present Value of Costs |

Under conditions of fixed budget, the objective is to select the combination of projects which give the maximum Net Present Value for the budget available. This is usually, but not always the same projects which would be selected by descending order of $B / C$ ratio. Generally the $\mathrm{B} / \mathrm{C}$ ratio should be expressed to no more than 1 decimal place since they are rarely more accurate and usually less than this.

The MicroBencost model is the present standard for benefit cost analysis in the Ministry. It is supported by Transport Canada, the U.S. FHWA and is widely used in other Provinces. The model is presently in U.S. units but a metric version is nearing completion. Data requirements are similar to most benefit cost models.

An interim default file for B.C. will be supplied for use with the MicroBencost model. The general principle is to use default data where better data is not available or where most of the inputs do not change between the base and proposed case. The data inputs and defaults are defined in more detail below.

Data Requirements:

[^11]
### 5.2 Economic Data

The economic data include:
Current Year Benefits and costs over the analysis period are discounted to the current year specified in the model.

Horizon Year This is the last year of the analysis period. For the PHP analysis, the planning period is 25 years so the horizon year is 2022. A 25 year planning period is consistent with the South Coast Systems Plan and the Okanagan Valley Transportation Plan. For a project completed in 1999 for example, then the horizon year is 2024.

Discount Rate $8 \%$ - This is the time value of money. It excludes inflation. Typically the interest rate $=$ inflation + discount rate.

Year benefits If for example, construction is completed in 1997 then benefits begin in begin 1998.

Analysis Period Period over which benefits are measured, for example: ( 25 year planning period - 1 year of construction) $=24$ year analysis period

### 5.3 Project Data

These inputs to the model describe project geometry and are used by the model to calculate default accident rates and default speeds using the Highway Capacity Manual procedures. As a general principle, these inputs are not critical if the analyst overrides the default speeds and accident rates with more reliable data or observed values. The inputs below are shown as "user input" which must be supplied by the analyst and default or optional data which may be supplied by the user.

| construction period | default is 1 year <br> user input (urban or rural) <br> environment |
| :--- | :--- |
| length | user input - length of |
| default |  |

### 5.4 Vehicle Operating Costs

Unless there is a change in the length of an alignment, VOC usually makes up less than $5 \%$ of the change in user benefits between base and proposed case. The changes are not necessarily positive since projects often result in higher speeds leading to greater fuel consumption. In the analysis of the TCH the important factor will be to capture any changes in travel distance resulting from
improved alignments. A $1 \%$ reduction in the length of an alignment can easily increase project benefits by $10 \%$. While a $1 \%$ reduction is small it represents $1 \%$ of a very large accumulation in user costs (accident and time as well as VOC) over the life of a project and as a result, shows up as a large benefit.

MicroBencost calculates vehicle operating costs as a function of traffic and highway conditions. Components accounted for in the cost calculations include:

- Fuel
- Oil
- Tires
- Maintenance
- Use related depreciation

The variables used to predict consumption rates of each VOC component typically include:

- $\quad$ speed
- $\quad$ curvature
- $\quad$ number of stop cycles
temperature
- grade
- number of speed change cycles
- surface condition
- temperature

The general algorithm for estimating Vehicle Operating Cost (VOC) is:
VOC $=$ AADT $x$ distance $x$ consumption rate $x$ unit price
All of the variables are default values with the exception of unit prices. These are under review by BCTFA and MoTH, along with other default inputs but the following data are suitable in the interim for use in B.C.

| Vehicle Description | Fuel Cost ( $\$ /$ US.gal) | Oil Cost $(\$ / \mathrm{art})$ | Tire Cost (\$/veh) | Maint \& Rep Cost (\$/1000 mi) | Deprec Cost (\$/veh) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Small pass | \$2.27 | \$1.72 | \$240 | \$30 | \$12,000 |
| Med/large pass | \$2.27 | \$1.72 | \$300 | \$40 | \$17,000 |
| Pickup/van | \$2.27 | \$1.72 | \$400 | \$50 | \$20,000 |
| Buses | \$1.50 | \$0.91 | \$5,600 | \$250 | \$100,000 |
| 2-Axle Single Unit | \$2.27 | \$1.72 | \$2,400 | \$300 | \$25,000 |
| 3-Axle Single Unit | \$2.09 | \$3.40 | \$5,000 | \$350 | \$70,000 |
| 2-S2 Semi's | \$2.09 | \$3.40 | \$7,000 | \$315 | \$100,000 |
| 3-S2 Semi's | \$2.09 | \$3.40 | \$9,000 | \$315 | \$130,000 |
| 3-S3 Semi's | \$2.09 | \$3.40 | \$11,000 | \$315 | \$160,000 |
| A,B or C Train Doubles Other | \$2.09 | \$3.40 | \$15,000 | \$315 | \$150,000 |

Tire cost is for all tires on a vehicle including semi-trailers and full trailers, if applicable. For trucks, this is not only the cost of new tires but also includes 1.5 recaps for 2 -axle single-unit trucks and 2.5 recaps for all other truck types.

### 5.5 TRAFFIC

### 5.5.1 Vehicle Classification

Default vehicle splits, which can be overwritten by the analyst, are available for the following vehicle types:

Passenger Vehicles:
Typical default values are shown here. There is no separate provision for Recreational Vehicles in the Benefit Cost model. If RV's are an issue they can be added in as single unit trucks rather than ignore them. The value of time and vehicle parameters for

| Vehicle | \% of Fleet | Occupancy |
| :--- | :---: | :---: |
| Small Pass | 17.4 | 1.3 |
| Med/large Pass | 50.8 | 1.3 |
| Pickup/van | 31.8 | 1.3 |
| Bus | 1.0 | 20 | single unit trucks should be changed accordingly. It is recommended that the working group responsible for standardizing benefit cost add an RV category this category to the BC default values.

Trucks:
The analyst should have reasonable estimates for traffic growth and \% trucks, in particular an estimate of 3-S2 or larger trucks is desirable since these have the greatest impact on vehicle operating costs and capacity (the default is $10 \%$ ). Theses default truck configurations are supplied with the BC default data. For most applications, the analyst does not need to classify the configuration. The overall \% trucks is adequate. The BC defaults assume trucks are split:

$$
\text { 2-Axle } \quad 7 \%
$$

3-Axle
3\%
2-S2 5\%
2-S3
40\%
3-S3 20\%
3-S3-S2 25\%
Other configurations may also be added if desired.

### 5.5.2 Traffic Growth

Traffic growth must be specified by the analyst It can be given as:

1. the base year traffic and an annual growth rate;
2. a base, intermediate, and horizon year traffic; or
3. as traffic volumes given for each year of the analysis period.

In the absence of structures traffic forecast, the first approach is most commonly used by
 planners. This approach has a tendency to overstate traffic in later years of the analysis period since it is a compound growth rate. The second approach is preferred since it assumes a straight linear growth which is usually closer to the truth. Traffic normally grows linearly or in a sigmoidal curve with slow growth initially, followed by e period of rapid growth as activity centers develop; followed by slow growth as the traffic patterns mature.

### 5.5.3 Traffic Profiles

Traffic profiles are the hourly traffic pattern over the average day or year. They characterize the variation in traffic flow over time to account for peak period congestion which increases the time and VOC cost per vehicle. The profile is entered as a histogram with 24 intervals and can either represent the average daily traffic pattern or the annual distribution. The profile for counter P21-1 at Monte Creek is illustrated here in an annual distribution. Default profiles are also available in the model if no profile is specified.

When traffic peaking is a concern, the annual traffic profile is usually the preferred approach. Converting the 8,760 hour/year profile from a permanent counter to a smaller number of intervals (up to 24) can be done by:

1. ranking the hour counts in descending order
2. divide them into 24 groups of 365 hours each
3. average the hourly traffic for each group.
4. convert the average to $\mathrm{a} \%$ of AADT
5. enter the \% of AADT into the model for each interval

The summation of the traffic over the 24 intervals $=\sum_{1}^{24} \% A A D T_{n} \times 365$ should equal the total annual traffic. Some minor adjustment is usually necessary. The analyst may also use variable duration groups

## Annual Traffic Profile - Monte Creek

| Traffic <br> Interval | \% of AADT | Traffic <br> Interval | \% of AADT |
| :---: | :---: | :---: | :---: |
| 1 | $11.88 \%$ | 13 | $3.66 \%$ |
| 2 | $9.25 \%$ | 14 | $3.09 \%$ |
| 3 | $8.17 \%$ | 15 | $2.50 \%$ |
| 4 | $7.39 \%$ | 16 | $2.04 \%$ |
| 5 | $6.86 \%$ | 17 | $1.66 \%$ |
| 6 | $6.49 \%$ | 18 | $1.35 \%$ |
| 7 | $6.14 \%$ | 19 | $1.08 \%$ |
| 8 | $5.81 \%$ | 20 | $0.90 \%$ |
| 9 | $5.45 \%$ | 21 | $0.76 \%$ |
| 10 | $5.09 \%$ | 22 | $0.64 \%$ |
| 11 | $4.68 \%$ | 23 | $0.53 \%$ |
| 12 | $4.23 \%$ | 24 | $0.36 \%$ |

### 5.5.4 Speed/Flow Relationships

Time savings typically make up $60 \%$ of project benefits. They are measured as the difference in travel time between the existing base case highway and the proposed case option. The best way to measure the travel speed for the base case is to drive the analysis section in the typical peak period and in the off-

Length of Grade for trucks to Slow to Crawl Speed

| Grade | Length <br> $(\mathrm{km})$ |
| :--- | :--- |
| $3 \%$ | 1.3 |
| $4 \%$ | 1.2 |
| $5 \%$ | 0.9 |
| $6 \%$ | 0.75 |
| $7 \%$ | 0.65 |
| $8 \%$ | 0.5 |
| $8 \%$ | 0.4 | peak periods and modify the default speed/volume curves in the model to agree with the observed speeds and volumes. Speeds for the proposed case cannot be measured directly. The recommended way is to use the default HCM calculations in the model or to measure speeds on a comparable highway at a different location. If the HCM calculations are used, TAC recommends using level terrain for all generalized terrain calculations since the HCM overstates the impact of terrain type on capacity ${ }^{14}$. For modeling purposes, specify $0 \%$ grade for generalized sections, and use the actual grade on specific grades which are long enough to reduce trucks to crawl speed ${ }^{15}$.

### 5.5.5 Passing Lanes or Short 4 Lane Sections

Passing/climbing/descending lanes will likely be one of the interim options considered for the TCH. The impact of passing lanes varies depending on volume, vehicle mix and grades and it is difficult to make a single generalization for use in benefit cost. The general approach is to estimate the impact of passing lanes using traffic simulation models, then input the speeds into a benefit cost model.

The TRARR model is used in various Provinces for this purpose and has been refined over the years to include better speed prediction, particularly for downhill operation. Properly calibrated, it remains the best tool for evaluating passing lane options. It has been used for Monte Creek to Revelstoke and in Revelstoke National Park. The outputs from TRARR include the estimates of changes in travel speed which are a required input for benefit costs analysis. Some typical speed increments are shown below:

[^12]

Depending on traffic volume, the typical increases in travel speed in the treated direction range from 1 to $4 \mathrm{~km} / \mathrm{hr}$ over the passing lane plus its effective downstream distance. If the treated section is a short 4 lane section, then the benefits apply to both directions.

If a TRARR simulation is not possible, this chart (taken from other TRARR simulations) could be used as a guide to evaluate passing lanes in MicroBencost by using it to modify the speed volume curve. The proposed case speed/volume curve for MicroBencost would be the base case plus these incremental speeds. These incremental speeds could be applied to the same passing lane + effective downstream distance where the downstream distance is estimated as the lesser of the distance to the next passing lane or:

$$
\text { Downstream Distance }=10 \mathrm{~km}-\text { AADT/1,500 }
$$

This accounts for platoons which reform more rapidly as traffic volume increases.

### 5.5.6 Access

The impact of access on operating speeds is of interest where an improvement includes frontage roads or median barriers. Traffic normally slows down in response to accesses whether or not there is traffic on them. Field studies by the Texas Transportation Institute ${ }^{16}$ calculated a relationship between the 85th percentile operating speed and access density for tangent roadways:

$$
\begin{gathered}
\mathrm{V}^{85}=74.91+22.29 / \mathrm{AD} \\
\text { where } \mathrm{AD}=\text { access density in } \\
\text { approaches } / \mathrm{km}
\end{gathered}
$$

AD is assumed to represent the access on both side for undivided highways and the right side only on divided highways.

[^13]
### 5.5.7 Summary of Traffic Inputs

Traffic data inputs may be grouped as default or required data:
Default data is supplied by the model and may be replaced by better observed data if it is available and likely to make a difference to the analysis. The default values usually make little difference to the analysis unless they are likely to change between the base and proposed case.

Required data must be entered by the analyst. Default vehicle classification data is supplied by the model but it is recommended that some vehicle classification data be collected since this will have a large influence on highway performance in mountainous terrain.

The required and default data are summarized below:

### 5.5.8 Value of Time

The recommended value of time are:
$\$ 10.00$ per person hour for passenger vehicles and buses.
$\$ 25.00 / \mathrm{hr}$ for Single Unit Trucks
$\$ 28.00 / \mathrm{hr}$ for Multiple Unit Trucks
These do not include the value of time for cargo

Values of time in MicroBencost are not differentiated by trip purpose since this varies considerably by time of day, day of week, and other categorizations. To correctly take into account the variations by time of day and day of week, it would be necessary to determine the percent of work/non-work, number of passengers by type, etc. by hour of day and day of week and to make calculations in the program for each subcategory. If this distinction is required, it should be calculated outside the model and input as a single average value.

## Adjustments to Time Value for Congestion

MicroBencost allows adjustments to the value of time for congestion. These adjustments are applied uniformly to all vehicle types. The adjustments can be categorized by volume/capacity ratio and rural or urban areas. It is recommended that these adjustments be kept to the default value of 1.0 . As facilities reach capacity, delay increases exponentially. Adding a congestion multiplier compounds this effect and exaggerates benefits beyond reasonable limits.

## Adjustments to Time Value for Stopping/Stopped Time

MicroBencost allows adjustments for stopping and stopped time at intersections, which is applied uniformly to all vehicle types. The default value of 1.5 is recommended.

## Adjustments for Discomfort

A separate discomfort cost is used for pavement roughness. It is recommended that the default roughness values be used as an interim measure. The defaults are constant over the planning period. Introducing roughness as a cost tends to distort user benefits depending on when the overlay is done in the base case.

### 5.6 Accident Costs

Accident Cost savings are determined by the unit costs of accidents and the accident rates and severities before and after the improvement.

### 5.6.1 Unit Costs

|  | 1996 |
| :---: | :---: |
| Fatal | $\$ 4,168,964$ |
| Injury | $\$ 97,076$ |
| PDO | 6,012 |

Unit costs by accident severity are comprehensive costs recommended in 1991 by Miller ${ }^{17}$ and updated to September 1996 based on Consumer Price Index (CPI). Fatal Accident costs are about $30 \%$ higher than those used prior to 1997. The lower value was 1 standard deviation below the statistical value of life generated by Miller. The higher value represents the median value and a move toward full cost accounting in transportation.

[^14]
### 5.6.2 Base Case Accident Rates

Accident rates are expressed as accidents/million vehicle $\mathrm{km}(\mathrm{a} / \mathrm{mvk})$ for highway sections and should include intersection accident rates unless there is a need to analyze intersections separately. If intersections need to be analyzed separately, as in the case of an interchange project, then intersection accident rates may also be specified in the MicroBencost model as accidents/million vehicles ( $\mathrm{a} / \mathrm{mv}$ ).

For sections or intersections, it is preferable to use the actual accident rate for the base case if the sample size is large enough. Large enough is a matter of degree but statisticians consider a sample size less than 25 to be "small". A sample size less than 25 should not be used to establish a rate. If there are less than 25 accidents recorded for an analysis section or intersection, then the options in order of preference are:

1. Use a longer period of record
2. Use a longer section of road
3. Use the TAC default rates ${ }^{18}$ (appendix B) by facility type

A longer period of record or section of road can be used as long as it is representative of the current conditions at the analysis section. A longer period of record may overstate the accident rate for PDO accidents since the minimum reporting level was raised from $\$ 400$ to $\$ 1,000$ on January 1, 1991.

### 5.6.3 Base Case Accident Severity

For benefit cost analysis, accident severity is the proportion of fatal, injury and property damage only (PDO) accidents. In statistics, the sample size required to estimate the proportion increases as the proportion diminishes or as the required accuracy increases. The formula for calculating the required sample size is:

$$
N=\left[t^{2}{ }_{95 \%} \times P \times(1-P)\right] / d^{2}
$$

where:
$\mathrm{N}=\quad$ sample size required to estimate the proportion
$\mathrm{t}_{95 \%}=$ the t statistic for ( $\mathrm{N}-1$ ) degrees of freedom and the $95 \%$ confidence interval ( $\mathrm{t}_{55 \%}=1.960$ for large samples)
$\mathbf{P}=$ assumed population proportion expressed as a decimal typically .01 for fatal accidents
$\mathrm{d}=\quad$ Desired precision. The precision is in the same units as the proportion.

[^15]If for example the estimated proportion of fatal accidents is .01 and the desired precision is $+/-$ .005 then required sample size (fatal + injury + PDO) is :

$$
\mathrm{N}=\left[1.960^{2} \times .01 \times(1-.01)\right] / .005^{2}=1,521 \text { accidents }
$$

 proportions at the $95 \%$ confidence interval for example are shown here.

| Error | Required Sample Size |  |  |
| :---: | :---: | :---: | :---: |
| 0.005 | 1521 | 33975 | 34482 |
| 0.01 | 380 | 8494 | 8621 |
| 0.05 | 15 | 340 | 345 |
| 0.1 | 4 | 85 | 86 |

The following guidelines apply for estimating base case accident proportions for benefit cost analysis:

- Use the Provincial default values for estimating proportion of fatal accidents. Sample sizes at any single location are generally not large enough.
- Use observed data for estimating proportions for injury and for PDO accidents if there are more than 50 total accidents in the sample. This will give an error of about $+/-13 \%$ on the injury and PDO accidents.
- If the sample size is <50 use Provincial averages for the proportion (see table below) or use judgement in the case of low volume rural roads where obvious safety problems exist.

## Accidents by Known Highway Class and Severity

BC Provincial Averages For Highway Sections Excluding Intersections 1991-1995

|  | Fatal |  | Injury |  | PDO |  | Total |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  |  | 2456 | $43.9 \%$ | 3122 | $55.7 \%$ | 5600 | $9.2 \%$ |  |
| Urban Freeway | 22 | $0.4 \%$ | 3706 | $41.4 \%$ | 5166 | $57.6 \%$ | 8961 | $14.6 \%$ |
| Urban Expressway (Multilane) | 89 | $1.0 \%$ | $1.0 \%$ | 1792 | $37.5 \%$ | 2933 | $61.5 \%$ | 4774 |
| Urban Conventional (2 lane) | 49 | $1.8 \%$ | $7.8 \%$ |  |  |  |  |  |
| Rural Freeway | 85 | $1.4 \%$ | 2529 | $41.0 \%$ | 3554 | $57.6 \%$ | 6168 | $10.1 \%$ |
| Rural Expressway (Multilane) | 39 | $2.0 \%$ | 878 | $43.9 \%$ | 1085 | $54.1 \%$ | 2002 | $3.3 \%$ |
| Rural Conventional (2 Lanes) | 699 | $2.1 \%$ | 12079 | $35.9 \%$ | 20854 | $62.0 \%$ | 33632 | $55.0 \%$ |
| Total | 983 | $1.6 \%$ | 23440 | $38.3 \%$ | 36714 | $60.1 \%$ | 61137 | $100.0 \%$ |

|  | Fatal |  | Injury |  | PDO |  | Total |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Freeway | 107 | $0.9 \%$ | 4985 | $42.4 \%$ | 6676 | $56.7 \%$ | 11768 | $19.3 \%$ |
| Multilane Undivided | 128 | $1.2 \%$ | 4584 | $41.8 \%$ | 6251 | $57.0 \%$ | 10963 | $17.9 \%$ |
| 2 Lane | 748 | $2.0 \%$ | 13871 | $36.1 \%$ | 23787 | $61.9 \%$ | 38406 | $62.8 \%$ |
| Total | 983 | $1.6 \%$ | 23440 | $38.3 \%$ | 36714 | $60.1 \%$ | 61137 | $100.0 \%$ |

|  | Fatal |  | Injury |  | PDO |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Urban | 160 | $0.8 \%$ | 7954 | $41.1 \%$ | 11221 | $58.1 \%$ |
| Rural | 823 | $2.0 \%$ | 15486 | $37.0 \%$ | 25493 | $61.0 \%$ |
| Total | 983 | $1.6 \%$ | 23440 | $38.3 \%$ | 36714 | $60.1 \%$ |

### 5.6.4 Proposed Case Accident Rate

Algorithms for estimating the accident rate for the proposed case are contained in appendix B and $\mathbf{C}$ taken from $\mathrm{TAC}^{19}$. Appendix B contains formulas for generalized highway improvements where the entire highway classification is changed. The algorithms in Appendix C can be used to estimate accidents for site specific improvements such as curve straightening, lane widening, shoulder paving etc.

The algorithms in appendix B compare favorably with the BC Provincial averages below:

|  | All <br> Accidents <br> $(\mathrm{a} / \mathrm{mvk})$ | Section <br> Accidents | Intersection <br> Accidents $^{\mathrm{a}}$ <br> $(\mathrm{a} / \mathrm{mv})$ |
| :--- | :---: | :---: | :---: |
| Urban Freeway | 1.0 | 0.5 | $\mathrm{n} / \mathrm{a}$ |
| Urban Expressway (Multilane) | 1.5 | 0.5 | 0.7 |
| Urban Conventional (2 lane) | 1.4 | 0.5 | 0.6 |
| Rural Freeway | 0.6 | 0.4 | 0.7 |
| Rural Expressway (Multilane) | 1.2 | 0.5 | 0.5 |
| Rural Conventional (2 Lanes) | 0.7 | 0.5 | 0.5 |

${ }^{\text {a }}$ Intersection accidents are only calculated for major roads not local access. They are expressed as number of accidents per million main road vehicles.

### 5.6.5 Proposed Case Accident Severity

In order of preference, the options for estimating the distribution of fatal, injury and PDO accidents for the proposed case include:

1. The reduction factors in appendix $\mathbf{A}$ or $\mathbf{B}$ when they are given separately by accident severity
2. For spot improvements use the same severity as the base case proportions
3. For changes in highway or intersection service class use the Provincial averages by highway or intersection class.

### 5.6.6 Intersections

When intersections or interchanges need to be analyzed separately, such as for an interchange project, then intersection accident rates are needed. These are usually expressed as accidents/million vehicles ( $a / \mathrm{mv}$ ) where the number of vehicles is the sum of the main road and side road vehicles entering the intersection.

[^16]Intersection accidents are more complex than section accidents and there are no simple quantitative relationships to predict the effects of specific intersection improvements. Accident rates will vary depending on :

- minor road volumes
- Major Road Volumes
- left turn protection
- sight distance at the intersection
- environmental conditions

Default accident rates are provided in MicroBencost but some additional research which may provide more accurate estimates or current estimates of intersection accident rates are given in appendix B from the TAC recommendations.

### 5.6.7 Reporting the Benefit Cost Results

The results of the benefit cost analysis can be kept simple but should include:

1. List of major assumptions which differentiate the base case from the proposed case.
2. Summary of results
3. Interpretation of the results - what accounts for the benefits in each category
4. Digital Files from the benefit cost model

An example of items 1 to 3 is presented in appendix $D$.

### 6.0 Multiple Account Evaluation

### 6.1 Introduction

Multiple account evaluation (exhibit 6.1) is a multi-criteria decision matrix tool to:

- provide a balanced view to decision makers--understanding the inevitable trade-offs which are required in any decision
- compare options within a project
- draw comparisons with other projects
- facilitate comparison with other program needs (such as health, education and social services)

MAE is most effective at the systems, reconnaissance or corridor level study where a broad range of corridor options are examined.

### 6.2 System Level Options

For the TCH corridor, options exist at both the system level and at the corridor level. It is not intended here to evaluate the broader system level options, which include for example:

1. Improve the TCH
2. Transfer truck traffic to rail
3. Improve the viability of highway 3 as an alternative to highway 1
4. Transportation Demand Management

The intention is to outline an evaluation framework for corridor level options associated with the first system level option of upgrading the TCH.

### 6.3 MAE Accounts

Five accounts typically used in the multiple account evaluation (MAE) are:

- Financial
- Customer service
- Social/Community
- Economic Development
- Environmental

A sixth account, infrastructure stewardship, may also be used in cases where the difference between options is due to deferred maintenance practices or the ability of an option to perform well if assumed future parameters change beyond expectation (e.g. demand) and whether the option could be modified later without great expense.

The most important accounts for the TCH will be the financial, customer service and environmental accounts.

Exhibit 6.1
Typical Multiple Account Evaluation

| ACCOUNT OPTION | Base Case | 1 <br> Passing Lanes then 4 lanes | $2$ <br> Pass.Ln. converted to 4 lanes | 3Staged4 LaneSections | Bypass Option |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | Existing Route | Bypass Route |

|  | $\bullet$ | Poor |  |  |  |  |

### 6.4 Financial Account

This is the cost to the infrastructure provider(s) of each option. It is expressed as a life cycle cost which is the present value of capital costs (class D estimates), periodic rehabilitation costs and annual operating costs discounted at $8 \%$ over a 25 year planning period to 1997 dollars. The financial costs are standard outputs from the MicroBencost model and can be used directly in the MAE chart. Financial costs do not differentiate between who pays. Cost shared amounts with other agencies for example should not be excluded from the project cost. The evaluation frameworks are presented in Chapter 6.

| Region | $\$ / 2$-Lane-km | $\$ / 4$-Lane-km |
| :---: | :---: | :---: |
| 1 and 6 | $\$ 9,100$ | $\$ 12,100$ |
| 2 and 3 | $\$ 7,800$ | $\$ 10,400$ |
| 4 and 5 | $\$ 8,400$ | $\$ 11,400$ |

These are the maintenance costs used for 1995 capital programming ${ }^{20}$, for winter class A highways. Costs are likely to be twice as high in extreme winter maintenance areas.

Resurfacing costs were assumed to be $\$ 60,000 / 2$ Lane-km for hot mix resurfacing with 15 years between resurfacings. Pavements resurfaced near the end of the planning period are assigned a salvage value equal to:

Salvage value of resurfacing $=$ Resurfacing cost $\mathrm{x} \boldsymbol{n} / 10$
where n is the number of years remaining to the end of the planning period. For example, $\mathrm{n}=2$ for a highway resurfaced in 2020 and a planning period ending in 2022.

Salvage values of other components are discussed in chapter 7.

### 6.5 Customer Service Account

This is the cost to highway users and includes dollar values for:

- Time
- Accident
- Vehicle operating costs

These are standard outputs from the MicroBencost model. The values from the model may be entered directly into the MAE table in the same way as the financial costs.

Highway closures on the TCH during avalanche conditions, landslides, traffic accidents or other causes are a regular occurrence. If reliability is to be a distinguishing feature between options, then the customer service account should show this as a separate item. The dollar

[^17]cost of closures is difficult to estimate since it varies depending on the decision to wait, divert or postpone a trip which in turn depends on the duration and location of the closure. The best option is usually to simply identify the annual duration of closures.

### 6.6 Social/Community Account

This documents external effects of highway projects on the communities and social values.
Noise, Visual and Pollution Impacts:

- Exposure - The number of residences and number of businesses adjacent to the highway quantifies how many will be directly influenced by noise, visual impact and pollution. This can be done with a drive-by survey.
- Magnitude - Changes in AADT indicate the magnitude and direction of the impacts for each option.

## Community Displacement

This is measured as the number of property takings associated with each option. These are typically assessed in the planning stages of a project and can be quantified for example:

| Total takings | 46 |
| :--- | :---: |
| Business takings | 4 |
| Residential takings | 42 |
| Partial takings | 27 |
| Special Purpose takings | Golf course |

## Community Severance Effect

Constructing a new transportation right of way through an existing community can limit access to pedestrian or local vehicle traffic to major generators and attractors in the community. Qualitatively, a bypass reduces community severance by reducing through traffic volume. Improving the existing route through town generally increases the barrier effect of the route. This can be summarized on an MAE chart as:

- good - reduces barrier effects
- fair - little or no change
- poor - increases barrier effects

## Consistency with Community Plans

This is rated by comparing options to Official Community Plans, Major Street Network Plans and Regional Growth Strategies where they exist. Consistency is evaluated qualitatively, based on the location, role, and impact of proposed transportation works relative to where they were envisioned in the plans. This can be summarized on an MAE chart as:

- good - project agrees with community plans
- fair - project is not addressed in the community plan
- poor - project is not consistent with community plans

## Equity

This highlights changes which benefit one group possibly at the expense of another. A bypass for example benefits residents of the bypassed community and through traffic at the expense of local businesses who depend on through traffic for business. If the issue is to be addressed in the economic development account, then it should not be repeated here. The MAE chart can summarize this by identifying the major impact group(s) and whether the impact is:

- good - positive impact
- fair - neutral
- poor - negative impact

## Visual Impacts

This may include for example:
Obstruction More desirable views are blocked by structures with no aesthetic value.

Intrusion This is a broader concept than visual obstruction. It relates to the perceived loss of amenity by people located close to a road and its traffic. It includes loss of privacy, night time glare from street and vehicle lights and the changed character of the landscape (i.e. from natural to modified).

Overshadowing A structure, such as an embankment or overhead bridge, reduces the amount of direct sunlight on an occupied property. This impact is not likely to be of importance in the TCH corridor and can be excluded.

For presentation in the MAE chart, impacts may be given as:

- good - improves visual qualities (i.e. by removing undesirable structures)
- fair - little or no change
- poor - visual impact is negative

### 6.7 Economic Development Account

This account documents the real income and employment benefits of alternatives to the Provincial economy. Income and jobs generated during highway construction for example are a benefit to a regional economy but not to a Provincial economy. From a Provincial perspective, the jobs created in one region are considered a loss to the other regions so there is no net gain from the construction.

Economic development benefits are generated when a highway improvement project results in lower out-of-pocket costs for transportation and health care due to lower time, accident and vehicle operating costs to the highway users. "Out-of-pocket" costs are the portion of highway user costs for which there is a market. Property damage, health care and lost productivity resulting from an accident for example are a real cost to the economy. Pain and suffering though, are not a cost to the economy, even though people demonstrate a willingness to pay to avoid pain and suffering. The reason is that there is no market associated with pain and suffering.

A rough estimate of the savings in out-of-pocket costs over a 25 year planning period can be calculated directly from the customer service accounts as:

```
Out-of-pocket cost savings
= Total time cost savings x (% trucks x truck value of time)/(% trucks x truck value
of time + % cars x car value of time)
+ Total accident cost savings x 35%
+ Total vehicle operating cost savings x 100%
```

The rationale for these proportions is explained in table 6.1
To apply the formula, asume for example, a project with $10 \%$ trucks and typical values of time shows the following comprehensive benefits:

Time savings $\$ 1.0$ million
Accident Savings $\$ 2.0$ million
Vehicle Operating Costs Savings $\$ 0.5$ million
Then the out-of-pocket costs savings are:

```
\(=\$ 1.0\) million \(\times(10 \%\) trucks \(\times \$ 28 / h r) /(10 \%\) trucks \(\times \$ 28 / h r+90 \%\) cars \(\times \$ 10 / h r)\)
\(+\$ 2.0\) million \(x\) 35\%
\(+\$ 0.5\) million \(\times 100 \%\)
\(=\$ 1.4\) million
```

Table 6.1
Rational for Out-of-Pocket Proportion of User costs

| User Cost | Out-of-Pocket Proportion |
| :---: | :---: |
| Time | This is the portion of the traffic stream for which travel time savings can be translated directly into additional marketable productivity. This is approximated as the value of time savings to trucks. The equation represents the lower bound of the estimate since it excludes some cars which also fall into this category. |
| Accident | Accident costs in benefit cost analysis are "comprehensive" costs which means they include non-market costs for pain and suffering as well as market costs for property damage, health care, lost production etc. The market cost or "out-of-pocket" cost of accidents is about $35 \%$ of the total based on the typical composition of comprehensive accident costs ${ }^{21}$ : <br> 3.4\% Medical and rehabilitation <br> $13.8 \%$ Wages and household Production <br> $0.3 \%$ Emergency services <br> 0.7\% Workplace <br> 2.3\% Administrative and legal <br> 0.6\% Travel delay <br> 11.5\% Property damage <br> 2.3\% Other <br> 65.1\% Pain, suffering and lost quality of life <br> 100\% |
| Vehicle Operating Costs | $100 \%$ of the savings in vehicle operating cost savings are considered as savings in "out-of-pocket costs". Commercial vehicles are able to translate $100 \%$ of vehicle cost savings directly into increased productivity or lower cost of production. For non-commercial traffic there are savings in the variable portion of vehicle operation (fuel, maintenance, use-related depreciation ) in the short run and savings in fixed costs (ownership, insurance etc.) in the long run. |

The Provincial economic benefits (discounted total for the planning period) are calculated from the out-of-pocket costs as:

Economic development benefits
= Out-of-pocket cost savings $x$ economic multiplier
$=\$ 1.4$ million $\times 1.68=\$ 2.35$ million

[^18]| Industry | Multiplier |
| :--- | :---: |
| Agriculture and related |  |
| services | 1.74 |
| Logging and forestry | 1.94 |
| Food and Beverage | 1.78 |
| Other Manufacturing | 1.74 |
| Construction | 1.49 |
| Wholesale and retail trade | 1.39 |
| Average | 1.68 |

The economic multiplier accounts for the indirect benefits when the out-of-pocket cost savings are re-spent several times on other goods or services. These multipliers are calculated periodically for each industry in the Provincial economy by BC Stats using a provincial input/output model ${ }^{22}$. The savings from highway improvements are eventually passed on to all consumers in the form of lower tax burdens for health care and lower prices (hence greater demand) for those goods for which rely more heavily on highway transportation. Some of the industries which intuitively depend on highway transportation are identified here. For planning purposes, the average of these industries, 1.68 , is used.

Regional or local economic benefits are more difficult to estimate. The major impact group includes businesses that rely on drive-by traffic (gas stations, restaurants, hotels). Qualitatively, the impact may be negative if the option is a community bypass and positive if the existing alignment is improved. Quantitatively, the impact is the number of businesses on the affected route.

| Improvement | Qualitative impact | Quantitative |
| :--- | :---: | :---: |
| Community Bypass | negative | \# of businesses |
| Improve existing route through town | positive | \# of businesses |

If better information is not available, a crude estimate of the rate at which jobs are created from the economic development benefits is the Provincial gross domestic product divided by Provincial employment. Gross domestic Product is the value of all goods and services produced in the province.

Provincial Employment 1.73 million
Provincial Gross Domestic Product $\$ 99.9$ billion
GDP/job $=\$ 76,800 / \mathrm{job}$
Using this estimate, the number of permanent jobs created by economic development is:
\# jobs $=$ Economic development benefits/(pwf x $\$ 76,800)$
where $\mathrm{pwf}=10.675$ is the present worth factor of a 25 year stream of benefits at an $8 \%$ discount rate and the economic development benefits are given as the total for the 25 year planning period.

[^19]
### 6.8 Environmental

This account helps document the nature, degree and mitigation of the major environmental impacts. Monetization of these impacts is possible using unit costs ${ }^{23}$ presented in appendix E . Monetized environmental costs have not yet been formally adopted by the Ministry but it would be consistent with the policy of full cost accounting for transportation projects. Monetized environmental costs have the potential to change the outcome of project evaluations, particularly where they involve new routes or environmentally sensitive areas.

In the interim, non-dollar measures are used but monetized environmental costs should be considered on a project by project basis.

| Impact | Measure |
| :---: | :---: |
| Land <br> Requirements | The requirements are quantified in hectares by land use, to the extent that different land uses can be defined. For example: <br> - Wetland <br> - Agricultural <br> - Forest <br> - Park/Protected Area <br> - Developed land <br> - Total |
| Noise | This is already included in the Social/Community Account as traffic volume and number of residences/businesses impacted. |
| Energy Consumption | Fuel Consumption is calculated by MicroBencost. |
| Emissions | Emissions of CO are calculated by MicroBencost. |
| Visual | Included in the Social/Community Account |
| Site Rehabilitation | Cleanup of contaminated sites prior to construction. Not expected to be an issue in the TCH -Kamloops to Alberta |
| Wildlife | Wildlife impacts include roadkill of migratory animals and habitat fragmentation related to new roads. In general, animals grow accustomed to transportation routes and tend to stay away from them. However, new routes are notorious for initial high rates of roadkill. |
| Water Pollution | Water quality impacts can all be measured quantitatively after the fact using accepted quantity, chemical and observation techniques. Predicting the impact prior to implementing a project is more problematic. The measure of impact is more likely to be the degree of avoidance and mitigation measures required in advance of a project. |

[^20]| Special Areas | The MAE should report special areas, their importance and whether <br> the impact is positive, negative or neutral. Special areas may include <br> sites of cultural, spinitual, historic, aesthetic, archaeological, special <br> ecological, botanical, geological, scientific or recreational importance. <br> The importance of special sites is specific to each case and can only be <br> evaluated by people who have experience and knowledge of it. If they <br> have not been previously identified, special sites are often identified <br> through public consultation. |
| :--- | :--- |

For the purpose of summarizing complex environmental impacts on a one page MAE table, a simple presentation is needed. For example:

| Good | Low impact due to direct effects. <br> Mitigation of impacts feasible and <br> cost effective |
| :--- | :--- |
| Fair | Medium impacts due to direct <br> effects. Mitigation of impacts is <br> possible and should be considered |
| Poor | High impacts due to direct effects. <br> Mitigation opportunities are limited |

### 6.9 Presenting the MAE Results

The MAE results are summarized in a single chart similar to exhibit 6.1. Monetary impacts are presented as dollars, quantifiable impacts as numbers and qualitative impacts as symbols. For each impact shown in the chart, there is normally an accompanying text supporting the rating given in the chart.

## 7. Option Analysis Framework for Benefit Cost

### 7.1 Corridor Level Options

The cost of upgrading the TCH means the corridor is likely to be done in stages rather than as one project. Conceptually there are several options leading to the ultimate development. The ultimate development is the plan beyond which no further highway improvements are anticipated.

| Option | Description |
| :--- | :--- |
| Base Case | Do the minimum to maintain and operate the highway |
| Option I. <br> Staged improvements <br> which are not part of the <br> ultimate option | Passing lanes for example built in stage 1, which are <br> abandoned in stage 2, may be less costly to build today but <br> the investment is lost when the second stage is implemented. |
| Option 2. <br> Staged improvements <br> incorporated as part of <br> the ultimate development <br> option | Some or all of the improvement made today will form a part <br> of the ultimate plan. If passing lanes for example were <br> constructed in stage 1, so as to be part of an ultimate 4 lane <br> concept in stage 2, then the cost of the four laning at the <br> beginning of stage 2 is reduced accordingly |
| Option 3. <br> Build the ultimate option <br> in stages (short 4 lane <br> sections) | If the ultimate plan is a 4 lane highway, then this option <br> would be to build short 4 lane sections in stages. |
| Option 4 <br> Build a bypass route | Most likely a combination of a new alignment combined with <br> improvements to the existing route. |
| Option 5 <br> Build a new route <br> Abandon the old | This might apply to Kicking Horse Pass where a new <br> alignment is built and the old alignment is abandoned. |

### 7.2 Base Case

The base case usually represents the "do-minimum" scenario. This generally includes normal maintenance, periodic resurfacing costs plus some allowance for capital replacement such as bridges or major structures which must be done if the route is to remain functional. There is usually no change, other than traffic growth, which would affect highway user costs.

### 7.3 Staged Improvements Which are not Part of the Ultimate Option

Climbing lanes for example, which do not get used in the ultimate design, may be less costly to build in the first stage but the investment is lost when the second stage is implemented.

Benefit cost models cannot analyze multiple stages in a single model run. The internal algorithms do not allow basic highway parameters to change more than once in the analysis period. The general approach is to handle each stage as a separate project and then add the results from each stage together as one project.

The important points in modeling the benefits and costs are:

- Both stages have a common base year (1997) and a common base case which is the existing road with no improvements.
- The construction value of the passing lane in phase 1 has no salvage value at the end of phase 1 because it is no longer used and it is not sold.
- Salvage value of the land can be included at the end of the 1st stage but the same number must be added as a cost at the start of the second phase and recovered again as salvage value in year 25 .
- Construction of the 4 lane section must start before or in the last year of the benefit period of the passing lane, if the 4 lane section is to open in the next year.

For example, a passing lane commissioned in 1999 and replaced by a 4 lane section in 2009 would be analyzed two stages.

Stage 1

|  | Base case | Proposed case |
| :--- | :---: | :---: |
| Base Year | 1997 | 1997 |
| Construction begins | nil | 1998 |
| Year Benefits begin | 1999 | 1999 |
| Horizon year | 2008 | 2008 |
| Maintenance cost | $\$ 30,000 / \mathrm{yr}$ | $\$ 30,000 / \mathrm{yr}$ |
| Resurfacing cost | $\$ 120,000$ in year 2002 | none |
| Capital Cost | nil | $\$ 3$ million |
| Salvage Values <br> construction <br> property | nil | nil |
|  | nil | nil <br> default |

Stage 2

|  | Base Case | Proposed Case |
| :--- | :---: | :---: |
| Base Year | 1997 | 1997 |
| Construction Begins | nil | 2007 |
| Year Benefits begin | 2009 | 2009 |
| Horizon year | 2022 | 2022 |
| Maintenance cost | $\$ 30,000 / \mathrm{yr}$ | $\$ 50,000 / \mathrm{yr}$ |
| Resurfacing cost | $\$ 120,000$ in year 2017 | $\$ 200,000$ in 2023 |

| Capital Cost | \$1.0 million bridge <br> repairs in 2015 | Stage 2 design + <br> construction + <br> stage 1 property <br> cost |
| :---: | :---: | :---: |
| Salvage Values <br> construction <br> property | nil <br> nil | default <br> 1997 value |

### 7.4 Staged Improvements Incorporated as Part of the Ultimate Development Option

This would be similar to a case where initial passing lanes are constructed so that they can be incorporated into the ultimate 4 lane design. The approach to the analysis is similar except for the capital cost of the stage 1 passing lane and the four lane section in stage 2 . Most likely the cost of the initial passing lane will be higher and the cost of the ultimate 4 lane section will be lower. The salvage value of the passing lane is still zero since its value is captured as the reduced capital cost for the 4 lane section.

### 7.5 Build the Ultimate Plan in Stages

If the ultimate improvement is built in stages, for example short 4 lane sections, then benefits of each stage begin in the year it is commissioned and continue to the end of the 25 year planning period (year 2022) and the default salvage values are used. A separate analysis is done for each stage and the present values for all stages are added together to get the total benefits and total costs.

### 7.6 Bypass

For analysis purposes, a bypass is any new alignment constructed without removing the old alignment from service. MicroBencost can analyze both routes simultaneously or independently. Regardless of the approach, the key is to include agency and user costs associated with both the old and the new alignment since both will remain in service. On the TCH traffic can be split logically between the two routes based on available origin destination data.

### 7.7 Build a New Route and Abandon the Old

The ultimate route is built in one stage on a new alignment and the old one is abandoned. Since the old alignment does not remain in service, this does not have to be treated as a bypass problem. It can be analyzed as if the existing route were being upgraded. The base case assumes the characteristics of the old alignment as if it were to continue in service. The proposed case is analyzed with the alignment, capacity and maintenance cost characteristics of the new route. The benefits begin in the year the new alignment is commissioned and continue to the end of the 25 year planning period (year 2022). Default salvage values are used. The restoration cost of the abandoned route can be included in the initial project cost as
a separate item with no salvage value. If the abandoned ROW is sold, the proceeds can be used to offset the cost of the property for the new alignment. If the old alignment is transferred to recreational use, the benefits associated with this transfer should be shown in the social account and the costs in the financial account.

### 7.8 Property Purchase

Conceptually there are two options for meeting future land requirements:

1. Land Banking for future use
2. Buy as required

The practical argument for buying land in the first stage of construction for use in the second stage is usually the difficulty associated with coming back a second time to expropriate additional land for the second stage.

The economic argument for buying land now for a need in the future is similar to any other highway project. The objective is to maximize the net present value of the investment. This occurs when the first year rate of return exceeds the discount rate. In the case of property, when the annual increase (less inflation) in property value exceeds the $8 \%$ discount rate, and is expected to continue to do so until the land is needed for construction, then it should be purchased. When the choice is vacant land now or developed land later, then the rate of increase is likely much greater than $8 \% /$ year and the decision to purchase now is justified. There is little value to a house or business purchased later for use as a highway.

When the first stage of a project includes purchasing land needed for the second stage, then the first stage should not be presented as a stand alone project. The cost of the additional land would otherwise distort the cost of the first stage. The approach is similar to the analysis used in section 6.3 where the present value of costs and benefits of the two stages are added together and presented as a single project.

The salvage value of the land at the end of the planning period should not be increased to market values. Uniess the highway is closed and the land sold, the salvage value remains as the value of the land continuing in its use as a highway. The default calculation done in MicroBencost yields a salvage value close to the original purchase price.

NOTES:

- All figures are asof July 1st of the year stated.
- 1976, 1981, and 1986 figures include estimates of the net census undercount and nonpermanent residents.
- 1991 figures include estimates of the net census undercount.
- Reference date for projection data is July 1.
- 1996 to 2021 projections are from P.E.O.P.L.E. ProjectionSeries 21.
-LastUpdated: April 1996

## A. 2 Municipal Population Statistics

Road sections with populations greater than 5,000 are considered as "urban" classification

|  |  |  |  | Mission | DM | - |

Dewdney-Alouette and Central Fraser Valley Regional Districts have been eliminated and apportioned to the Fraser Valley and Greater Vancouver Regional Districts.
\# The Fraser-Cheam Regional District was renamed the Fraser Valley Regional District after its amalgamation with the Central Fraser Valley and a portion of Dewdney-Alouette.

The accidents rates recommended in the TAC document for use in Microbencost are drawn from research in several Provinces and States, relying heavily on BC and Ontario data. They are presented here as accidents per km per year but must be converted to an accident rate of accidents per 100 million vehicle miles for use in Microbencost. The conversion formula is:
accidents/100 million veh-miles $=160.9 \times$ accidents/(km-year) $\times 1,000,000 /(365 \times$ AADT $)$
Accident rates are given separately for intersections and sections since Microbencost allows the accident rates to be entered this way if desired.

## B. 1 Highway Sections

## B.1.1 Two Lane Rural Roads.

The recommended model for estimating accidents that do not occur at intersections is:
Accidents $/(\mathrm{km}$-year $)=\mathrm{Ax}(\mathrm{AADT})^{\mathrm{b}}$

|  | All Accidents |  |  |  | Fatal and Injury Accidents |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Lane <br> Width $(\mathrm{m})$ | $>6.1$ | $<6.1$ | $>6.1$ | $<6.1$ | $>6.1$ | $<6.1$ | $>6.1$ | $<6.1$ |
| Shoulder <br> Width $(\mathrm{m})$ | $<1.8$ | $<1.8$ | $>1.8$ | $>1.8$ | $<1.8$ | $<1.8$ | $>1.8$ | $>1.8$ |
| b | 0.733 | 0.892 | 0.733 | 0.892 | 0.783 | 0.971 | 0.783 | 0.971 |
| A | 0.00287 | 0.00096 | 0.00250 | 0.00069 | 0.00067 | 0.00018 | 0.00054 | 0.00012 |

The equivalent accidents per 100 million vehicle miles for use in Microbencost is shown below.

## B.1.2 Two Lane Urban Roads.

The recommended model for estimating accidents that do not occur at intersections is:

Accidents/(km-year) = 0.00369 (AADT) ${ }^{0.72}$

The equivalent accidents per 100 million vehicle miles for use in Microbencost is shown here.

| AADT | total | Fatality | Injury | PDO |
| :---: | :---: | :---: | :---: | :---: |
| 1,000 | 235.2 | 1.65 | 90.0 | 143.5 |
| 2,000 | 193.7 | 1.36 | 74.1 | 118.2 |
| 3,000 | 172.9 | 1.21 | 66.2 | 105.5 |

|  |  |  |  |  |

## B.1.3 Multilane Roads Without Full Access Control.

These geneally represent the expressway classification. Below about 18,000 AADT there are more accidents on highways with a median barrier than without due to an increase in collisions with the median barrier. The recommended model for estimating accidents that do not occur at intersections is:

Accidents $/ \mathrm{km} / \mathrm{yr}=\mathrm{a}(\mathrm{AADT})^{\mathrm{b}}$

| Accident Type | Area Type | Divided or Undivided | a | b |
| :--- | :---: | :---: | :---: | :---: |
| Total | Urban | D or U | 0.0000524 | 1.146 |
| Total | Rural | D | 0.0084885 | 0.618 |
| Total | Rural | U | 0.0000560 | 1.129 |
| Fatal + Injury | Urban | D or U | 0.0001045 | 0.980 |
| Fatal + Injury | Rural | D | 0.0013000 | 0.687 |
| Fatal + Injury | Rural | U | 0.0000078 | 1.219 |

Multilane Roads without Full Access Control
(Excluding Intersection Accidentss)
$\mathrm{a} / 100 \mathrm{mvm}$

## B.1.4 Freeways

These are generally a depressed median highway with full access control. The recommended model for estimating accidents that do not occur at interchanges is:

| Accident Type | Lanes | a | b |
| :--- | :---: | :---: | :---: |
| Total | 4 | 0.0000474 | 1.155 |
| Total | $>4$ | 0.0000978 | 1.113 |
| Fatal + Injury | 4 | 0.0000206 | 1.136 |
| Fatal + Injury | $>4$ | 0.0000122 | 1.212 |

Accidents $/ \mathrm{km} / \mathrm{yr}=\mathrm{a}(\mathrm{AADT})^{\mathrm{b}}$

The equivalent accidents per 100 million vehicle miles for use in Microbencost is shown below.

## 4 lane rural freeways with full access control

(excludes interchange accidents)
$\mathrm{a} / 100 \mathrm{mvm}$

| AADT | total | Fatality | Injury | PDO |

Urban freeways with full access control and more than 4 Lanes
(excludes interchange accidents)
$\mathrm{a} / 100 \mathrm{mvm}$

## B. 2 Highway Intersections

## B.2.1 Rural Intersections

| Intersection Type | Rate (accidents/yr) ${ }^{\text {a }}$ | Severity |  |
| :---: | :---: | :---: | :---: |
| Rural Unsignalized Four leg intersection of undivided roads ${ }^{25}$ |  <br> For three legged intersections divide rate by 2.4 <br> For divided roads multiply rate by 2.6 <br> (These 2 adjustment factors were taken directly from TAC ${ }^{24}$ ) | Fatal Injury PDO | $\begin{aligned} & 0.017 \\ & 0.342 \\ & 0.641^{26} \end{aligned}$ |
| Rural Intersection, Signalized ${ }^{27}$ | Accident/yr $=0.00703\left(\text { AADT }{ }_{\text {majo r raad }}\right)^{0.51}\left(\text { AADT }_{\text {minor r rad }}\right)^{0.29}$ | Fatal Injury PDO | $\begin{aligned} & 0.017 \\ & 0.342 \\ & 0.644^{18} \end{aligned}$ |
| Rural Interchange ${ }^{29}$ | Accidents/yr $=0.04864 \times\left(\text { AADT }{ }_{\text {maior road }} / 1,000\right)^{1.337}$ | Fatal Injury PDO | $\begin{aligned} & 0.012 \\ & 0.370 \\ & 0.619^{30} \end{aligned}$ |

${ }^{2}$ For use in Microbencost, the above rates must be converted to accidents per million vehicles as:
$\mathrm{a} / \mathrm{mv}=\mathbf{a c c i d e n t s} /$ year $\times 1,000,000 /(365 \times$ (Major road AADT + Minor Road AADT)

[^22]
## B.2.2 Urban Intersections, Unsignalized ${ }^{31}$

Yield Controlled

| Major | Minor Street ADT |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Street ADT | 100 | 300 | 500 | 700 | 900 | 1250 |
| 500 | .31 | .48 | .62 | .76 | .90 | 1.20 |
| 1000 | .34 | .6 | .75 | .88 | 1.00 | 1.16 |
| 1500 | .40 | .68 | .86 | 1.04 | 1.10 | 1.26 |
| 2000 | .46 | .71 | .94 | 1.15 | 1.20 | 1.31 |
| 2500 | .50 | .75 | .98 | 1.19 | 1.29 | 1.36 |
| 3000 | .53 | .77 | .99 | 1.20 | 1.31 | 1.38 |
| 3500 | .56 | .79 | 1.01 | 1.22 | 1.33 | 1.4 |

Stop Controlled (4 leg, 2-way stop)

| Major | Minor Street ADT |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Street ADT | 100 | 300 | 500 | 700 | 900 | 1250 |
| 500 | .12 | .21 | .27 | .34 | .40 | .49 |
| 1000 | .25 | .31 | .37 | .41 | .49 | .61 |
| 1500 | .34 | .42 | .49 | .55 | .72 | .76 |
| 2000 | .41 | .52 | .61 | .70 | .79 | .90 |
| 2500 | .49 | .58 | .69 | .79 | .89 | 1.04 |
| 3000 | .52 | .64 | .80 | .95 | 1.03 | 1.15 |
| 3500 | .54 | .70 | .90 | 1.11 | 1.17 | 1.22 |

## B.2.3 Urban Intersections, Signalized

The TAC report did not find any satisfactory research for predicting accidents at urban intersections. The default values in Microbencost are recommended as the interim values.

[^23]
## B.2.4 Railroad Crossings

Crossbuck

| AADT Range | Fatal | Injury | PDO |
| :---: | :---: | :---: | :---: |
| $0-1,999$ | 2.00 | 22.8 | 36.9 |
| $2,000-3,999$ | 0.89 | 10.1 | 16.4 |
| $4,000-7,999$ | 0.44 | 5.1 | 8.2 |
| $8,000-15,999$ | 0.38 | 4.3 | 7.0 |
| $16,000-23,999$ | 0.24 | 2.7 | 4.4 |
| $24,000-35,999$ | 0.17 | 2.0 | 3.2 |
| $36,000-57,999$ | 0.13 | 1.5 | 2.4 |
| $58,000-75,999$ | 0.10 | 1.2 | 1.9 |
| $76,000+$ | 0.09 | 1.1 | 1.7 |

Gate

| AADT Range | Fatal | Injury | PDO |
| :---: | :---: | :---: | :---: |
| $0-1,999$ | 0.93 | 10.6 | 17.2 |
| $2,000-3,999$ | 0.40 | 4.6 | 7.4 |
| $4,000-7,999$ | 0.27 | 3.0 | 4.9 |
| $8,000-15,999$ | 0.17 | 1.9 | 3.1 |
| $16,000-23,999$ | 0.11 | 1.2 | 2.0 |
| $24,000-35,999$ | 0.07 | 0.8 | 1.3 |
| $36,000-57,999$ | 0.05 | 0.6 | 1.0 |
| $58,000-75,999$ | 0.04 | 0.5 | 0.8 |
| $76,000+$ | 0.04 | 0.5 | 0.7 |

The TAC document pointed out that the RR grade crossing accidents for a gate controlled crossing were higher than for a crossbuck sign only. This has been corrected in later versions of the model. The correct defaults for the RR grade crossing accident rates are shown here.

## C. 1 Introduction

This section presents accident reduction factors (ARFs) which are multipliers used to assess the safety impact of specific improvements including:

1) Lane widening and shoulder upgrading
2) Safety resurfacing
3) Installation of climbing lanes
4) Installation of passing lanes
5) Mitigation of collision with fixed roadside objects
6) Installation of roadway illumination
7) improvement of horizontal curvature
8) Measures to reduce intersection accidents
9) Installation of median barriers
10) Widening narrow bridges

The general algorithm is:
Proposed case accident rate
= Base case accident rate
$\times$ Target accident proportion
x Accident reduction factor
The target accident proportion is all accidents unless otherwise noted in the remarks accompanying each table. For left turn treatments for example, the target accidents are the proportion of left turn accidents at the intersection. Information on target accidents for BC is found in "1989-1993 Annual Accident Statistics on Numbered Highways" ${ }^{33}$.

If multiple countermeasures at a site are used, they are not additive. Run-off-road (ROR) accidents on a curve for example can be addressed by curve straightening, shoulder widening and lane widening. The overall reduction for ROR accidents which could be expected is:

$$
A R F=A R F_{1} \times A R F_{2} \times A R F_{3}
$$

[^24]where:
ARF = overall reduction factor for ROR accidents due to all 3 countermeasures.
$A R F_{1}=$ reduction factor for the largest countermeasure.
$\mathrm{ARF}_{2}=$ reduction factor for the next largest countermeasure.
$\mathrm{ARF}_{3}=$ reduction factor for the smallest countermeasure.
If for example three countermeasures were proposed with individual accident reduction factors of say $91 \%$ for curve straightening, $93 \%$ for lane widening and $95 \%$ for improving lateral clearance, then their combined effect is to reduce the accident rate to .84 of the base case rate.
$$
\text { ARF }=.95 \times .93 \times .91=.804
$$

The accident reduction factors which follow are the summary of current research but should be interpreted as guidelines in the absence of better information.

## C. 2 Lane Widening And Shoulder Upgrading

Target Accident Reduction Factors For Lane And Shoulder Widening On 2 Lane Roads

| Condition |  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| Before | After | Pessimistic | Most Likely | Optimistic | Remarks |
| $\leq 9 \mathrm{ft}$ lanes, <br> no shoulder | 11 ft lanes, <br> no shoulder | 0.77 | 0.73 | 0.66 | Same factors <br> apply for |
| $\leq 9 \mathrm{ft}$ lanes, <br> no shoulder | 11 ft lanes, <br> 4 ft shoulder | 0.60 | 0.52 | 0.40 | paved and <br> unpaved <br> shoulders |
| $\leq 9 \mathrm{ft}$ lanes, <br> no shoulder | 11 ft lanes, <br> 6 ft shoulder | 0.50 | 0.40 | 0.25 |  |
| 11 ft lanes, <br> no shoulder | 11 ft lanes, <br> 4 ft shoulder | 0.71 | 0.65 | 0.57 |  |
| 11 ft lanes, <br> no shoulder | $11 \mathrm{ft} \mathrm{lanes}$, <br> 6 ft shoulder | 0.60 | 0.52 | 0.40 |  |

## C. 3 Safety Resurfacing

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| Fatal and Injury <br> Accidents | 1 | 0.9 | 0.85 | Applies to wet <br> pavement accidents |
| Property Damage <br> Accidents | 1 | 0.85 | 0.80 |  |
| All Accidents | 1 | 0.85 | 0.80 |  |

This reduction factor should be used with care since there is likely to be an increase in dry weather accidents associated with the higher speeds on the resurfaced pavement.

## C. 4 Passing or Climbing Lanes

The safety impact of auxiliary lanes is treated in three parts:

1. 2.0 km upstream of the treated section
2. The treated section
3. A downstream section over which platooning is reduced

## C.4.1 Treated section

The following values from TAC were deduced from examination of both climbing and passing lane studies. Auxiliary lanes generally reduce accidents within the treated section due to the wider crossection and recovery area compared to the surrounding two-lane sections. The factors apply across all accident severities at the treated section.

Climbing Lanes

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| Fatal and Injury <br> Accidents | 0.90 | 0.85 | 0.80 | Applies to total <br> accidents at target <br> locations |
| All Accidents | 0.95 | 0.90 | 0.85 |  |

Passing Lanes

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| Fatal and Injury <br> Accidents | 0.85 | 0.75 | 0.70 | Applies to total <br> accidents at target <br> locations |
| All Accidents | 0.90 | 0.80 | 0.75 |  |

## C.4.2 Upstream Section

Passing lanes are normally posted 2.0 km in advance of the treated section. This reduces the tendency of drivers to make risky overtaking maneuvers in this 2.0 km section. The normal rate of passing related accidents in BC is $2 \%$ to $4 \%$ of accidents ${ }^{34}$. For planning purposes a $2 \%$ accident reeducation is assumed in the 2.0 km section in advance of a passing lane.

## C.4.3 Downstream Section

Auxiliary lanes provide some benefits downstream of the treated section ${ }^{35}$ since platoons continue to be dispersed for some distance downstream depending on the traffic volume. Rear end type accidents, which are often attributed to following too close, make up about $10 \%$ of non-intersection accidents on rural 2 lane highways in B.C. ${ }^{36}$ Including rear-end and overtaking accidents, about $12 \%$ of accidents are related to platooning. An Auxiliary lane typically reduces platooning by about $25 \%$ immediately downstream of the treated section, which suggests an overall accident reduction of $25 \% \times 12 \%=3 \%$. Assuming this drops to $0 \%$ over the effective downstream length of an auxiliary lane, then the average reduction over this effective downstream length is $\mathbf{1 . 5 \%}$. Accident severity is assumed to be the same as the base case rate.

The effective downstream length is assumed to vary with AADT. At high volumes, platoons reform immediately downstream of the passing lane while at lower volumes, the effective distance can be several kilometers. The effective distance is estimated as the lesser of the distance to the next passing lane or:

$$
\text { Downstream Distance }=10 \mathrm{~km}-\mathrm{AADT} / 1,500
$$

If the treated section is a short 4 lane section then the downstream distance can be applied in both directions.

[^25]
## C. 5 Mitigation Of Accidents With Fixed Roadside Objects.

This includes collisions with utility and sign poles, fences, culverts, bridge supports, ditches and trees.

Target Accident Reduction Factors For Fixed Object Accidents

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| Fatal and Injury <br> Accidents | 0.80 | 0.60 | 0.50 | Applies to fixed <br> object accidents <br> at target locations |
| Property <br> Damage Only | 1.10 | 1.0 | 0.90 |  |

## C. 6 Installation Of Roadway Illumination

Target Accident Reduction Factors For Roadway Illumination

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| Fatal and Injury <br> Accidents | 0.70 | 0.60 | 0.40 | Applies to night <br> accidents at <br> target locations |
| Property <br> Damage Only | 0.95 | 0.85 | 0.65 | lannn |

## C. 7 Horizontal Curve Improvements

This includes minor improvements such as widening and curve warning and delineation. Since these cover a variety of improvements, they should only be used for crude estimation purposes only.

Target Accident Reduction Factors For Minor Improvements To Horizontal Curves.

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition | Pessimistic | Most Likely | Optimistic | Remarks |
| All Accidents | 0.90 | 0.75 | 0.60 | Applies for crude <br> estimation only |

## C. 8 Measures To Reduce Intersection Accidents

Target Accident Reduction Factors For Intersection Improvements

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition/Measure | Pessimistic | Most Likely | Optimistic | Remarks |
| Left Turn Lanes - <br> Signalized | 0.90 | 0.80 | 0.65 | For all severities, <br> apply to left turn <br> accidents |
| Left Turn Lanes - <br> Unsignalized | 0.70 | 0.50 | 0.40 | For all severities, <br> apply to left turn <br> accidents |
| Traffic Control <br> Signals (All <br> Severities Combined) | 2.00 | 1.60 | 1.40 | Apply to rear end <br> accidents |
|  |  | 0.50 | 0.25 | Apply to right angle <br> accidents |
| Illumination (All <br> Severities Combined) | 0.80 | 0.60 | 0.50 | Apply to night <br> accidents |

## C. 9 Installation Of Median Barriers

Target Accident Reduction Factors For Installation Of Median Barriers

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Condition/Measure | Fatal | Injury | PDO | Remarks |
| Median Width < 12 ft <br> Double Faced Beam Rail | 0.25 | 0.98 | 1.28 | Assumed to <br> apply to median <br> encroachment <br> accidents. |
| Median Width < 12 ft <br> Concrete Barrier | 0.10 | 0.90 | 1.10 | 1.30 |
| Factors have a <br> high variability |  |  |  |  |
| Median Width > 12 ft <br> Double Faced Beam Rail | 0.15 | 0.95 | N/A |  |
| Median Width $>12 \mathrm{ft}$ <br> Concrete Barrier | 0.15 | N/A | N |  |

Caution: Median barriers virtually eliminate cross-median accidents. These are usually severe, but very few. The barriers increase the total accident frequency by as much as $30 \%$ on access controlled roads and $50 \%$ on non access controlled roads. Vehicles are presumably colliding with the median barrier, where previously they might swerve into the opposing lanes and recover without incident.

## C. 10 Widening And Other Improvements To Narrow Bridges.

Target Accidents Reduction Factors For Narrow Bridge Improvements

|  | Accident Reduction Factor Estimates |  |  |  |
| :--- | :---: | :---: | :---: | :--- |
| Condition/Measure | Pessimistic | Most Likely | Optimistic | Remarks |
| Install Bridge and <br> Approach Rail | 0.55 | 0.40 | .10 | Accidents to side <br> of bridge |
|  | 0.65 | 0.55 | 0.30 | Accidents to end <br> or approach |
|  | 0.75 | 0.64 | 0.55 | Fatal accidents |
|  | 0.75 | 0.64 | 0.55 | Injury accidents |
|  | 0.85 | 0.75 | 0.70 | PDO accidents |

## Example Summary Report for the Benefit Cost Results

## Monte Creek Interchange (Hwy 1/97)

Highway 97 is a two lane rural arterial connecting to the 2 lane Highway 1 east of Kamloops. The existing at grade stop controlled T intersection will be replaced by a grade separated loop interchange with free flow on the NBLT, NBRT, EBST,WBST and EBRT. The WBLT has very low volume and will be connected into a frontage road crossing under Highway 1. There is a $7 \%$ grade descending from south to north toward the interchange which is a concern for heavy trucks trying to stop for the signals in the down hill direction. The grade is preceded by a brake check. Trucks also roll over or lose their loads on the EBRT as they try to maintain speed for the approaching hill on Highway 97 SB.

The problem is modeled as a 3.38 km highway segment with an interchange commissioned in 2002.

Key Assumptions

| Location | AADT |
| :--- | :---: |
| Highway 1 west of I/C | 9,748 |
| Highway 1 east of I/C | 6,482 |
| Highway 97 | 2,718 |
| Intersection Volume | 14,482 |

Traffic:

There are $5.8 \%$ trucks (from classification counts July 30, Aug 3, Aug 6/93).

| Movement | \% of <br> Intersection <br> Volume | Change in travel <br> distance <br> compared to base <br> case (km) |
| :---: | :---: | :---: |
| NBRT | $0.7 \%$ | -.722 |
| NBLT | $12.76 \%$ | -.323 |
| EBST | $36.6 \%$ | -.010 |
| EBRT | $13.8 \%$ | -.385 |
| WBST | $35.6 \%$ | -.010 |
| WBLT | $0.6 \%$ | +.746 |

Travel Distance.
The traffic splits and changes in travel distance due to the improved interchange flow are estimated here by turning movement.

## Accident rate

The base case Highway 1 sample size is 94 accidents in 9 years over a 1.85 km section with an accident rate of $1.02 \mathrm{a} / \mathrm{mvk}$. The proposed case Highway 1 section assumes this is reduced by $50 \%$ to $0.51 \mathrm{a} / \mathrm{mvk}$, approaching that of a typical freeway rate ( 0.4 to $0.5 \mathrm{a} / \mathrm{mvk}$ ). For analysis purposes, accidents on the Highway 97 approach are treated as intersection accidents. The sample includes 48 accidents at a base case rate of $.84 \mathrm{acc} / \mathrm{mv}$. The proposed case is assumed to reduce the accidents by $50 \%$ to $0.44 \mathrm{a} / \mathrm{mv}$.

## Accident Severity

The same accident severity is used for the base and proposed case section and intersection based on a sample of 142 accidents on the Hwy 1 and Hwy 97 approaches:

| fatal | $2.8 \%$ |
| :--- | :--- |
| injury | $47.9 \%$ |
| PDO | $49.3 \%$ |

## Project Costs

Costs are $\$ 24.4$ million spread out over 4 years starting in 1999 .

## Summary of Results

| Benefits | \$ Millions |  |  |
| :--- | ---: | :---: | :---: |
| Travel Time Savings | 6.5 |  |  |
| Accident Cost Savings | 16.0 |  |  |
| Veh.Op.Cost Savings | 1.8 |  |  |
| Costs |  |  |  |
| Total Benefits |  |  |  |
| a. Discounted Construction Costs | 24.3 |  |  |
| b. Discounted Salvage Value | 18.2 |  |  |
| c. Discounted Increase in Maintenance Costs | 2.7 |  |  |
| Total Discounted Costs a-b+c |  |  | -0.15 |
| B/C Ratio | 20.8 |  |  |
| NPV | 1.2 |  |  |
| Carbon Monoxide reduction (million kg.) | 0.6 |  |  |
|  | 0.26 |  |  |

## Interpretation of Results

Time saving benefits result from

- removing the interrupted flow for the NB left and right turns
- decreasing the travel distance (via the new ramps) for all intersection movements except the WBLT.

Safety benefits result from the lower accident rate associated with removing the at grade intersection and with the improved geometric design of the approaches.

Vehicle operating costs are the largest component of benefits and result from reducing the travel distance around the ramps and from eliminating stop and go operation associated with a stop controlled T-intersection. Savings include fuel savings of 4 million litres over the 20 year planning period. Reduction in CO may be used in the environmental account of the MAE.

## Appendix E <br> Environmental Costs

## Associated with Transportation ${ }^{37}$

Greenhouse gases. Automobiles produce several greenhouse gases, which are measured in terms of their $\mathrm{CO}_{2}$ equivalents. Current precautionary estimates place global warming damage costs at $\$ 1,000 /$ tonne of $\mathrm{CO}_{2}$ equivalent. The shadow price of these emissions is the same no matter where they occur.

Particulate. Fine particulate matter $\left(\mathrm{PM}_{10}\right)$ is the most significant of local air pollutants. Particulates attributable to mobile sources cause a number of deaths comparable to traffic crash fatalities in the region. Current estimates of mean values of mortality costs for the Lower Fraser Valley range between $\$ 0.3$ and $\$ 0.4$ billion per year, assuming $\$ 3$ million value of statistical life. The total mortality cost of fine particulate generated by vehicles is of the same order of magnitude as the mortality due to traffic accidents. The mortality cost per km depends on vehicle type, operating speed and emission control technology. For present and future vehicle technologies, diesel trucks and buses have the highest mortality rates per km driven. These vehicles are responsible for about half of the traffic related particulate in the Greater Vancouver Regional District at present. The statistics are not likely to improve in the future if vehicle travel keeps on increasing.

Ozone Depletion. Vehicles are major contributors to ozone depleting emissions through leaks and maintenance losses from automobile air conditioners. The shadow price of ozone depletion is high: preliminary estimates place it at $\$ 1,200$ per kg of CFC equivalent for each $1 \%$ of global GDP experienced as damage from the "ozone hole" in 1995. There are indications that the 1995 damage might be two to four times higher than 1\% GDP. In that case the annual damage from British Columbia light vehicles would about to $\$ 600$ million to $\$ 1.2$ billion. These costs accrue globally.

Ground Level Ozone. The economic costs of health, crop damage, material damage and visibility problems caused by smog are one order of magnitude smaller that the mortality and morbidity costs of fine particulate from traffic. While important for the sectors and communities affected, the preoccupation of major air quality management initiatives with these issues at the expense of more damaging pollution, is unjustified from scientific and administrative points of view.

[^26]Noise and Vibrations. Most of the existing estimates of noise costs are incorrect because they only consider a portion of the total damage costs. The density and sensitivity of the recipients to noise is as important a variable as traffic characteristics. The noise damage costs should therefore be expressed as costs per affected person. A shadow price of $\$ 1,000$ to $\$ 1,500$ per affected person per year is currently used in Scandinavian countries. This is likely a lower bound on the total damage cost of noise. Noise effect on wildlife is not known. Traffic induced vibrations do not likely cause building damage, but references disagree on the subject.

Land use Impacts. These impacts include the general impacts of low density urban expansion (urban sprawl) and specific damage to wildlife and greenspace that results from increased roads and automobile use. These can either be estimated based on a cost per hectare of land that is impacted or as a cost per vehicle-km. This cost most likely ranks higher than noise and below air pollution in terms of total cost. Indirect and cumulative impacts can be especially large if a project, such as a road capacity improvement, eliminates existing constraints to growth. In this case it can increase the speed and scale of development, causing significant indirect and cumulative land use impacts. If latent demand exists for development in an area, improved road access is almost certain to increase development and reduce external environmental benefits, even if land use management strategies are implemented.

Costs associated with converting various land uses to highways were presented in the report in $\$ /$ ha/year:

| Land Use | $\$ /$ ha/year |
| :--- | :--- |
| Wetlands | $\$ 30,000$ |
| Pristine wildland/urban greenspace | $\$ 24,000$ |
| Second growth forest | $\$ 18,000$ |
| Pasture/Farmland | $\$ 12,000$ |
| Settlement/Road buffer | $\$ 6,000$ |

Resources and Energy. Resource production and therefore consumption has external environmental and social costs. The best know of these are the externalities associated with energy consumption, which include environmental damage during production and processing spills, and various negative market impacts. These externalities are indicated by the general social support that has developed for energy conservation, recycling, and sustainable development. The indirect energy absorbed by transportation related activities, such as vehicle and fuel production and distribution, constitutes 20 to $45 \%$ of the energy consumed to propel vehicles. Personal vehicles use the most indirect energy and transit vehicles the least.

Waste Disposal. Automobiles use produces various wastes including used fluids, tires and junked vehicles. In the past many of these wastes were poorly managed, resulting in external costs. A variety of new programs and methods are now being used to reduce and internalize these costs, but these do not appear to be completely successful. A working value of $\$ 0.001$ per km is recommended, although it grossly underestimates the total cost.

Water Pollution and Hydrologic Impacts. Roads and automobile use cause water pollution and hydrologic impacts (changes in surface and ground water flow such as increased flooding and reduced ground water recharge). We estimate this cost to average $\$ 0.01$ to $\$ 0.02$ per average automobile km , and recommend an intermediate working value of $\$ 0.015$.

Barrier Effects. The barrier effect is the increased travel time discomfort and anger that roads and road traffic cause to pedestrians and bicyclists. Although methods for calculating the barrier costs to pedestrians and bicyclists are commonly used in Scandinavia, they are nearly unknown in North America. Based on the Scandinavian experience in Norwegian urban areas, the barrier costs are of the same order of magnitude as the total traffic noise damage costs to the communities. Road and transportation corridors also sever wildlife habitats and farming communities. Evaluation of these effects is ongoing in the Ministry of Transportation and Highways.

Impacts on Biodiversity. Through lost or degraded habitat and direct mortality of wildlife, transportation has a significant effect on the flora and fauna of British Columbia. While other chapters have accounted for reduced biodiversity through lost habitat and pollution, a model had been presented to calculate the cost on a site specific basis, of direct wildlife mortality resulting from traffic. This cost however, is a small fraction of the total value of biodiversity, which is not known and is not likely knowable. Based on the annual economic value of average habitat, the current total Canadian conserved nature area is worth as much as the national GDP.

[^7]:    ${ }^{9}$ In the 1995 PHP, gross domestic product (GDP) was also included as an independent variable in the previous 1995 PHP forecasts, but is not used in the 1997 PHP forecasts for three reasons:

    - GDP forecasts are only produced for 5 years and the planning period is 25 years
    - GDP is forecast for the Province as a whole while traffic is often specific to the economy or population of a region.
    * In the past, when calibrated against historical data, GDP did not significantly improve the fit of the forecast model.
